## Foreword

Editor's Note: Geographers are marked by a desire to explore, see, and understand both places and the relationships between human activities and the natural environment. Alexander von Humboldt (1769–1859) is significant to the study of geography due the breadth of his scientific inquiries and knowledge and his ability to integrate these studies within larger works that were both scientifically advanced and appealing to a wider nonspecialist public. He was known as a natural scientist of the highest order, working to unify studies of botany, zoology, and ecology, but also as a competent writer whose works provided a wide audience with their only glimpse of South America, a continent previously known to most only through myth and speculation. In Humboldt's introduction to *Personal Narrative of a Journey to the Equinoctial Regions of the New Continent*, he describes what the science of geography is all about, how a geographer works, and the rewards found in the study of the science.

TWELVE YEARS HAVE elapsed since I left Europe to explore the interior of the New Continent. From my earliest days I was excited by studying nature, and was sensitive to the wild beauty of a landscape bristling with mountains and covered with forests. I found that traveling out there compensated for a hard and often

agitated life. But pleasure was not the only fruit of my decision to contribute to the progress of the physical sciences. For a long time I had prepared my self for the observations that were the main object of my journey to the torrid zone. I was equipped with instruments that were easy and convenient to use, made by the ablest artists, and I enjoyed the protection of a government that, far from blocking my way, constantly honored me with its confidence. I was supported by a brave and learned friend whose keenness and equanimity never let me down, despite the dangers and exhaustion we faced.

Under such favorable circumstances, and crossing regions long unknown to most European nations, including Spain itself, Bonpland [Humboldt's companion] and I collected a considerable number of materials, which when published may throw light on the history of nations, and on our knowledge about nature. Our research developed in so many unpredictable directions that we could not include everything in the form of a travel journal, and have therefore placed our observations in a series of separate works.

Two main aims guided my travels ... I wanted to make known the countries I visited, and to collect those facts that helped elucidate the new science vaguely named the Natural History of the World, Theory of the Earth, or Physical Geography. Of these two aims, the second seemed the more important. I was

passionately keen on botany and certain aspects of zoology, and flattered myself that our researches might add some new species to those already known. However, rather than discovering new, isolated facts, I preferred linking already known ones together. The discovery of a new genus seemed to me far less interesting than an observation on the geographical relations of plants, or the migration of social plants, and the heights that different plants reach on the peaks of the cordilleras.

The natural sciences are connected by the same ties that link all natural phenomena together. The classification of species, which we should consider as fundamental to botany, and whose study has been facilitated by introducing natural methods, is to plant geography what descriptive mineralogy is to the rocks that form the outer crust of the earth. To understand the laws observed in the rocks, and to determine the age of successive formations and identify them from the most distant regions, a geologist should know the simple fossils that make up the mass of mountains. The same goes for the natural history that deals with how plants are related to each other, and with the soil and air. The advancement of plant geography depends greatly on descriptive botany; it would hinder the advancement of the sciences to postulate general ideas by neglecting particular facts.

Such considerations have guided my researches, and were always present in my mind as I prepared for the journey. When I began to read the many travel books ... I regretted that previous learned travelers seldom possessed a wide enough knowledge to avail themselves of what they saw. It seemed to me that what had been obtained had not kept up with the immense progress of several sciences in the late 18th century, especially geology, the history and modifications of the atmosphere, and the physiology of plants and animals. Despite new and accurate instruments, I was disappointed, and most scientists would agree with me that while the number of precise instruments multiplied, we were still ignorant of the height of so many mountains and plains; of the periodical oscillations of the aerial oceans; the limit of perpetual snow under the polar caps and on the borders of the torrid zones; the variable intensity of magnetic forces; and many equally important phenomena.

Maritime expeditions and voyages round the world have rightly conferred fame on naturalists and astronomers appointed by their governments, but while these distinguished men have given precise notions of the coasts of countries, of the natural history of the

ocean and islands, their expeditions have advanced neither geology nor general physics as travels into the interior of a continent should have. Interest in the natural sciences has trailed behind geography and nautical astronomy. During long sea voyages, a traveler hardly ever sees land; and when land is seen after a long wait, it is often stripped of its most beautiful products. Sometimes, beyond a sterile coast, a ridge of high mountains covered in forests is glimpsed, but its distance only frustrates the traveler.

Land journeys are made very tiresome by having to transport instruments and collections, but these difficulties are compensated by real advantages. It is not by sailing along a coast that the direction, geology, and climate of a chain of mountains can be discovered. The wider a continent is, the greater the range of its soil and the richness of its animal and vegetable products, and the further the central chain of mountains lies from the ocean coast, the greater the variety of stony strata that can be seen, which reveal the history of the earth. Just as every individual can be seen as particular, so we can recognize individuality in the arrangement of brute matter in rocks, in the distribution and relationships of plants and animals. The great problem of the physical description of the planet is how to determine the laws that relate the phenomena of life with inanimate nature.

In trying to explain the motives that led me to travel into the interior of a continent, I can only outline what my ideas were at an age when we don't have a fair estimate of our faculties. What I had planned in my youth has not been completely carried out. I did not travel as far as I had intended when I sailed for South America; nor did it give me the number of results I expected. The Madrid Court had given me permission in 1799 to sail on the *Acapulco* galleon and visit the Philippine Islands after crossing its New World colonies. I had hoped to return to Europe across Asia, the Persian Gulf, and Baghdad.

Having outlined the general aim, I will now briefly glance at the collections and observations we made. The maritime war during our stay in America made communications with Europe very uncertain and, in order for us to avoid losses, forced us to mail three different collections. The first we sent to Spain and France, the second to the United States and England, and the third, the most considerable, remained constantly with us. Toward the end of our journey, this last collection formed 42 boxes containing a herbal of 6,000 equinoctial plants, seeds, shells, and insects, and geological specimens from Chimborazo, New Granada

and the banks of the Amazon, never seen in Europe before. After our journey up the Orinoco, we left a part of this collection in Cuba in order to pick it up on our return from Peru and Mexico. The rest followed us for five years along the Andes chain, across New Spain, from the Pacific shores to the West Indian seas. The carrying of these objects, and the minute care they required, created unbelievable difficulties, quite unknown in the wildest parts of Europe.

Our progress was often held up by having to drag after us for five and six months at a time from 12 to 20 loaded mules, change these mules every eight to 10 days, and oversee the Indians employed on these caravans. Often, to add new geological specimens to our collections, we had to throw away others collected long before. Such sacrifices were no less painful than what we lost through accidents. We learned too late that the warm humidity and the frequent falls of our mules prevented us from preserving our hastily prepared animal skins and the fish and reptiles in alcohol. I note these banal details to show that we had no means of bringing back many of the objects of zoological and comparative anatomical interest whose descriptions and drawings we have published. Despite these obstacles, and the expenses entailed, I was pleased that I had decided before leaving to send duplicates of all we collected to Europe. It is worth repeating that in seas infested with pirates, a traveler can only be sure of what he takes with him. Only a few duplicates that we sent from America were saved; most fell into the hands of people ignorant of the sciences. When a ship is held in a foreign port, boxes containing dried plants or stones are merely forgotten, and not sent on as indicated to scientific men.

The same reasons that slowed our communications also delayed the publication of our work, which has to be accompanied by a number of engravings and maps. If such difficulties are met when governments are paying, how much more worse they are when paid by private individuals. It would have been impossible to overcome these difficulties if the enthusiasm of the editors had not been matched by public reaction.

In our publications, Bonpland and I have considered every phenomenon under different aspects, and classed our observations according to the relations they have with one another. To convey an idea of the method followed, I will outline what we used in order to describe the volcanoes of Antisana and Pichincha, as well as Jorullo, which of the night of the 20th of September 1759 rose 1,578 feet up from the plains of Mexico. We fixed the position of these remarkable

*Alexander von Humboldt was known as a preeminent geographer and a scientist of the highest order.*

mountains in longitude and latitude by astronomical observations. We took the height of different parts with a barometer, and determined the dip of the needle and magnetic forces. We collected plants that grew on the slopes of these volcanoes, and specimens of different rocks. We found out the exact height above sea level at which we made each collection. We noted down the humidity, the temperature, the electricity and the transparency of the air on the brinks of Pichincha and Jorullo; we drew the topographical plans of these volcanoes by measuring vertical bases and altitude angles. In order to judge the correctness of our calculations, we have preserved all the details of our field notes.

During my navigation up the South American rivers and over land, I had written a very brief itinerary where I described on the spot what I saw when I climbed the summit of a volcano or any other mountain, but I did not continue my notes in the towns, or when busy with something else. When I did take notes, my only motive was to preserve those fugitive ideas

that occur to a naturalist, to make a temporary collections of facts and first impressions. But I did not think at the time that these jotted-down notes would form the basis of a work offered to the public. I thought that my journey might add something to science, but would not include those colorful details that are the main interest in journeys. Since my return, the difficulties I experienced trying to write a number of treatises and make certain phenomena known have overcome my reluctance to write the narrative of my journey. I fear that for many years no foreign traveler will be able to

cross those countries I visited. I also venture to hope, once peace has been established, that my work may contribute to a new social order. If some of these pages are rescued from oblivion, those who live on the banks of the Orinoco or Atabapo may see cities enriched by commerce and fertile lands cultivated by free men on the very spot where during my travels I saw impenetrable jungle and flooded lands.

ALEXANDER VON HUMBOLDT  
PARIS, FEBRUARY 1812

## Introduction

GEOGRAPHY'S primary focus is “where?” This question has been an essential part of human history from its outset. Knowing where there was water, food, safety, where were the cities and best trade products and special raw materials, especially flint and later metal for tools, was crucial to human and cultural evolution. The need as well as the desire (curiosity) to explore new places and experiences would seem an ingrained human characteristic. Certainly, the ability to predict seasonal cycles for migration and foods—simple survival—elevated those who knew the answers to special, probably shamanistic or priestly, positions.

There is little in this world that is not geographic in some way. Anything that has a place, any place that has an impact on human history, or any human activity is geographic. Once the geographer knows where things are, the analytical focus becomes one of how humans and place are related or interact. For example, how do desert people adapt? How do they conserve and use water? How and when do they move? What kinds of shelter have they evolved?

Geography is one of those subjects essential to understanding virtually everything; yet as we witness in the daily news of events around the world, it is studied and understood by few policy makers and politicians or even journalists. Geography is a subject that encom-

passes all the topics necessary for the Renaissance person: familiarity with the natural environment, society, and knowledge of cultures, distant and near places, economics, politics, physics, the atmosphere, the literature of places and cultures as it reflects its environment, as well as the mapping and measuring of spatial distributions and relationships.

There was a time when geographers necessarily focused on collecting and inventorying facts and data about places because much of the world was unknown. This basic need has not generally passed. Even in the 21st century an inventory of the location and nature of places, peoples, economies, species, and so on, remains essential, especially given the high rate of change. Fortunately we have satellite images that reveal not only what is there but how it is changing and the rate of change, both natural and human caused.

Once they have a basic inventory of the planet, geographers can begin to focus on human and environmental relations and the interactions between geography and politics, economics, and warfare. In the past, the geographic inventory sometimes was used for military purposes. Other times it was used for trade and economics. In the past, maps were so valuable they became closely held state secrets. Today, the widespread availability of geographic data on the internet and the use of global positioning satellites (GPS) and geographic information systems (GIS) have even led

some to use latitude and longitude as their personal address. Travelers increasingly find GPS locations on signs in yacht harbors or desert road race landmarks. Computer mapping and satellite images have moved from the realm of military intelligence and the battlefield to applications in real estate and businesses as well as disease control, disaster monitoring and relief, and even hunting and fishing. Many large farmers in the U.S. Midwest now have GPS and GIS on their combines and tractors and use them to further increase their efficiency and productivity.

As the world has become more integrated via television, air travel and now the internet, knowledge of different places and cultures has likewise increased in value and necessity. Today, one may talk to a technician in India about a computer problem in the United States. Banks and institutions move money around the world in milliseconds. Tourists withdraw money from their local banks at bank machines all over the world. Cell phones are used by Mongol herdsmen in the middle of the Gobi to call relatives in Miami. Masai herdsmen in Kenya watch satellite television from around the world. Al Qaeda agents meet in Iguazu Falls to avoid Interpol and American security. Cell phones with cameras can be used to call home from virtually anyplace on the planet and may even send photos of people as well as places.

Most are familiar with the observation that those who ignore history are doomed to relive it, but we can add that those who ignore geography (distances, map projections, cultural distinctions, seasons, etc.) are doomed to face unnecessary difficulties and problems—personal, economic, and political. Certainly the economic and political events of the early 21st century continue to evidence this.

Geography and geographers are at the center of one of the newest and fastest growing industries in the world. The need to know where anything is—crime, raw materials, the enemy, political groups or voters—and then the total geographic context (when does a crime occur, what is the access to a raw material, what are the supply lines and disposition of an enemy, how have the voters voted and what are their ages, sex, ethnicity, etc.) is limitless. City planners need to know

where property lines, soil types, tax status zones, and utilities lines (both above and below ground) are to provide a range of services from schools and hospitals to police and fire rescue. Military uses of digital maps and GPS to send planes, missiles, and covert units to specific houses—even windows and doors—are seen on nightly television in both the real world and various forms of entertainment.

People ignorant of world places, distances, cultures, and religions continue to create unnecessary problems. It is our hope that this encyclopedia may help fill the gap. To that end we have included some 750 articles that describe places, concepts, theories, people, and themes in world geography. From the Fulda Gap to the Hudson River, just about all countries, territories, and land masses are profiled. Icon maps and some 200 graphics, maps, and photos complement the text. In addition, a complete world atlas is presented in an appendix. It is this thorough accumulation and carefully edited information that comprises the encyclopedia.

This encyclopedia and its various parts provide both a basic geographic definition and context for the most modern applications of geography to geopolitical aspects and geographic facts related to ancient as well as modern history. To avoid a purely European or American view, we have sought and included contributors from all areas of the world.

You can use this work to find out about places familiar and exotic. There are basic (traditional) definitions and facts. But, more important, you can also find explanations of historical context and politics as well as the terms and ideas of modern technology. For students, it is important to recognize that geography can be used to study the distant past, from the age of dinosaurs to the earliest humans and the earliest civilizations. Geography also is highly relevant to our world of multinationals, global terrorism, and geopolitics.

## Chronology of Geography

200 million B.C.E.

Present-day continents were part of a supercontinent known as Pangaea or Pangea (Greek for “all-Earth”). Over millions of years, this supercontinent broke up through the creation of rifts, cracks in the crust that moved apart and allowed magma to rise from lower levels and form new seabeds. Water moved into the broken landmass to form enclosed bodies of water such as the Gulf of Mexico and the Red Sea. A sufficiently large rift even formed the Atlantic Ocean.

2,000,000 to 18,000 B.C.E.

The last Ice Age was the most recent episode of global cooling of the Earth. Much of the world’s temperate zones were alternately covered by glaciers during cool periods and uncovered during the warmer interglacial periods when the glaciers retreated.

11,000 B.C.E.

Human beings began to domesticate and cultivate plants. This new activity, which eventually changed populations, lifestyles, and the environment in profound ways, proceeded in sporadic bouts. Although the development of agriculture took place over millennia on different continents, its initial beginning is sometimes referred to as the Agricultural Revolution.

3500 B.C.E.

The development of means of transportation, dating from the invention of the wheel, made it possible for the surplus from the countryside to feed urban populations, a system that continues to the present day.

3100 B.C.E.

Egypt appeared as a unified state around 3300 B.C.E. About 3100 B.C.E., Egypt was united under Menes, who inaugurated the 30 pharaonic dynasties in which Egypt ancient history is divided: the Old and the Middle Kingdoms and the New Empire.

2600 B.C.E.

The Indus Valley civilization prospered on the river plains and vicinity in what is western India and Pakistan. The early cities began to interact, creating a common urban culture that lasted about 700 years. The inhabitants were known as the Harappan or Indus culture, and it thrived contemporaneously with those of Mesopotamia and Egypt.

1300 B.C.E.

The recorded history of China dates back some 3,300 years, although modern archaeological studies suggest still more ancient origins in a culture that flourished between 2500 and 2000 B.C.E. Centuries of migration, amalgamation, and development created a distinctive

system of writing, philosophy, art, and political organization that came to be recognized as Chinese civilization.

1120 B.C.E.

Tiglath-Pileser I, the greatest of the Assyrian kings, crossed the Euphrates, defeated the kings of the Hittites, conquered Carchemish, and advanced on the coasts of the Mediterranean. He was the founder of the first Assyrian Empire.

356–323 B.C.E.

Alexander the Great created one of the most extensive empires in history, linking Greece and the Mediterranean to the Indus River and Central Asia.

384–322 B.C.E.

Aristotle hypothesized and scientifically demonstrated that the Earth had a spherical shape. Evidence for this idea came from observations of lunar eclipses.

138 B.C.E.

China's Zhang Qian sought to ally with the Yuezhi tribe in the west and set out on a journey of discovery, resulting in the Silk Road. He returned with no trade ally but with information about horses and tribes hitherto unknown. The emperor sent more expeditions in search of horses and luxuries. Although Zhang Qian is titled as the father of the Silk Road, he was not the first. Even before, Chinese merchants were providing small amounts of Chinese goods to the west via the Silk Road.

150 B.C.E.

From the second half of the 2nd century B.C.E., until the first century, the military campaigns that consolidated the Roman Empire helped the progress of geographic knowledge. The Greeks, as a mainly seafaring people, explored the coast lands; thanks to the Romans, knowledge of the inside lands also became known. The empire extended from England to the Caspian Sea and the Tigris-Euphrates Rivers and included all of North Africa.

150 B.C.E.

Ptolemy was the first to use latitude and longitude and measure them in degrees in his book *Geography*.

313 C.E.

The great advance of Christian expansion was the Constantine Edict in 313. From then on, Christianity

became the official religion of the Roman Empire. This was the start of an alliance between the church and political power that had a great impact on the diffusion of the Christian religion in the ancient world.

400–1300

Middle Ages (5th to 13th centuries) were a time of intellectual stagnation. In Europe, the Vikings of Scandinavia were the only group of people carrying out active exploration of new lands.

In the Middle East, Arab academics began translating the works of Greek and Roman geographers starting in the 8th century and also began exploring southwestern Asia and Africa. Some of the important intellectuals in Arab geography were Al-Idrisi, Ibn Battuta, and Ibn Khaldun.

570

Mohammed heralded the birth of Islam in the area of Mecca and Medina in Saudi Arabia. His influence spread to include all of North Africa, much of Mediterranean Europe, and parts of Central Asia, India, and China.

1100s

Chinese sailing fleets extended their trading missions into the Indian Ocean. Using Calicut in southwestern India as a base, they traveled north following the coast past the Persian Gulf and the southern Arabian Peninsula before heading south to Zanzibar on Africa's east coast.

1100s–1200s

The Crusades involved European kingdoms in the domestic affairs of the Middle East, especially Jerusalem and the Ottoman Empire, centered in the city of Constantinople.

1200s

The century saw the rise of the kingdom of Mali, based upon local gold resources and trade, especially with Arabia. This set the stage for the spread of Islam south of the Sahara.

1206–1350s

The Mongols created an empire that reached from China to Jerusalem and into Southeast Asia.

1300s–1400s

The kingdom and city of Great Zimbabwe reached its height of influence, with Swahili trade along the East

African coast, linking the kingdom to Oman, the Arabian Peninsula, and the coast of India.

### 1325

Born in Tangier, Morocco, Ibn Battuta was a famous Arab traveler and writer who explored in Africa, Europe, and Asia. Ibn Battuta's journey began in North Africa in 1325 with travels that included visits to Egypt, Syria, the Arabian Peninsula (Mecca), (north-eastern) Iran, (southern) Iraq, Red Sea, Yemen, East Africa, Asia Minor, Afghanistan, India, Bengal, Indonesia, China, and Spain. His travels ended in 1353 after a journey across the Sahara and western Africa.

### 1350–1918

The Ottoman Empire had a greater geographic extent than the Roman Empire and emphasized trade and science (navigation, mathematics, astronomy) as well as the arts and medicine. It stretched from the Moors in Spain to India and was ultimately focused on Constantinople in today's Turkey.

### 1400s

From the 15th century on, when ships became the dominant medium for commercial transport, coastal sites, such as Hormuz (Persian Gulf) and Gao (western India), were the main centers for interregional trade for the Indian Ocean. The importance of overland bases returned in the 19th century, however, as new fairs and entrepôts/emporia were established along railroad lines, such as Irkutsk and Vladivostok, which functioned as way stations for the Trans-Siberian Railroad.

### 1421–23

After nearly 400 years of sea trade with ports along the East African coast, Chinese Emperor Zhu Di commissioned Admiral Zheng He to explore and map the world. Recent archaeological findings suggest that Zheng He's great Treasure Fleet circumnavigated the globe, rounding the Cape of Good Hope in Africa and Cape Horn at the tip of South America before returning to China in 1423. It is from this voyage that Niccolò da Conti is believed to have constructed a map later used by Christopher Columbus when he set sail for the East Indies.

### 1400s–1600s

During the Renaissance, numerous journeys of geographical exploration were commissioned by a variety of nation states in Europe. Most of these voyages were financed because of the potential commercial returns

from resource exploitation. The voyages also provided an opportunity for scientific investigation and discovery and added many significant contributions to geographic knowledge. Important explorers of this period include Christopher Columbus, Vasco da Gama, Ferdinand Magellan, Jacques Cartier, Sir Martin Frobisher, Sir Francis Drake, John and Sebastian Cabot, and John Davis. Also during the Renaissance, Martin Behaim created a spherical globe depicting the Earth in its true three-dimensional form in 1492. Prior to Behaim's invention it was commonly believed in the Middle Ages that the Earth was flat. Behaim's globe probably influenced the beliefs of explorers of that time because it suggested that one could travel around the world.

### 1427–1521

The Aztecs created and ruled a major empire centered in what is today's Mexico.

### 1438–1525

The Incas created an empire that organized and ruled much of the Andes Mountains area in South America.

### 1453

With the conquest of the Byzantine capital, Constantinople, under the rule of Mohammed II (1451–81), famously known as “Mehmet the Conqueror,” the Ottomans extended their dominance over much of Anatolia and South Eastern Europe.

### 1492

Italian Christopher Columbus, sailing under a Spanish flag, discovers the New World.

### 1494

Portugal and Spain sign the Treaty of Tordesillas that established the Line of Demarcation. Crossing over present-day Brazil at the approximate longitude of 48 degrees, this meridian line granted to Spain new land to the west and to Portugal the discoveries to the east. Hence, following the landing by Pedro Álvares Cabral at Porto Seguro in 1500, Portugal claimed Brazil.

### 1500s

The 16th century saw the rise of many great kingdoms and empires in Southeast Asia. Many were the precursors of current states or countries.

### 1519

On September 20, 1519, five ships, the *Trinidad*, *San Antonio*, *Concepcion*, *Victoria*, and *Santiago*, along

with a crew of 270 men set sail under Ferdinand Magellan on a journey around the world full of mutiny, discovery, and death.

1530s

In the 1530s, Spanish conquerors subdued the Incas, bringing the Andes Mountains into Spain's New World empire. The Spanish often used systems of forced Native American labor to work in Andean silver mines. The native inhabitants did not always readily accept Spanish rule. In the 18th century, there were more than 100 native rebellions, including the great uprising led by José Gabriel Condorancú in 1780.

1543

The first to proclaim that the Earth and the other planets revolved around the sun was Nicolaus Copernicus, a Polish astronomer who published his theory in 1543, the year of his death. Copernicus also claimed that the Earth rotated on its axis. Additional support for Copernicus came from Johannes Kepler, a German astronomer who rejected Ptolemy's concept of circular revolution and proposed the idea of the elliptical motion of the planets. Finally, it was Galileo Galilei in Italy who demonstrated the accuracy of the Copernican theory.

1564

Gerardus Mercator was appointed court cartographer by Duke Wilhelm of Cleve. During 1564, the map *Angliae Scotiae et Hiberniae nova descriptio* was printed and in 1569 the great map of the world, *Nova et aucta orbis terrae descriptio*, in 18 sheets, was issued to help in navigation. Thanks to this work, Mercator is heralded as the founder of modern cartography.

1587–1621

The Iranian (Persian) city of Isphahan enjoyed its golden age of artistic and architectural achievement, begun under Shah Abbas during the period of the Safavid dynasty, established in Persia in 1502. Mosques, palaces, gardens and bridges were constructed; carpet-making and artistic endeavors were encouraged. Its population swelled to 600,000 and it became one of the great metropolises of the time.

1599

In Asia, chartered companies were trading for spices, textiles, and exotic merchandise like Chinese ceramics. The English East India Company was one of these and obtained a royal charter in 1599.

1603

Edo (as Tokyo was called until 1868) was founded and later became the largest city in Japan, and the largest or second-largest in the world, with a population exceeding one million by the 18th century.

1700s

The 18th century was the start of the industrial and transport revolutions—application of mechanical power to replace animal and human power and labor, leading to the rise of factories, unions, and the development of modern political philosophies.

1773

British naval captain James Cook is the first to cross the Antarctic Circle in 1773. Exploration of the region within the Antarctic Circle resumed in 1820 when the explorer Fabian Gottlieb von Bellingshausen received support from Russian Tzar Alexander I to explore the south polar region.

1788

British territorial acquisition was being consolidated in the South Pacific. Voyages to the Pacific increased British possessions with the discovery of Hawaii, French Polynesia, New Caledonia, New Zealand and the eastern Australian coast. A penal colony was established in New South Wales in 1788.

1792

One of the oldest sources of weather prediction in the United States is the *Old Farmer's Almanac*, an annual publication filled with advice for the self-sufficient. The *Almanac* claims an 80 percent success rate in forecasting the weather—18 months ahead—based on a secret formula devised by *Almanac* founder Robert B. Thomas around 1792.

1800

About 1800, Alexander von Humboldt, a German naturalist, noted the apparent fit of the bulge of eastern South America into the bight of Africa. On the basis of this observation, he theorized that the lands bordering the Atlantic Ocean had once been joined.

1800

Less than 3 percent of the world's population was living in cities of 20,000 or more; this increased to about 25 percent by the mid-1960s and to about 40 percent by 1980. It is estimated that now more than half of the world's population lives in the urban areas, with 90

percent living within 62 mi (100 km) of the coast or a navigable river.

1800

Napoleon's engineers revived the idea and construction of a canal linking the Mediterranean Sea and Indian Ocean (via the Red Sea). The eventual Suez Canal greatly changed maritime trade by reducing the need to go around the Cape of Good Hope at the southern tip of Africa.

1804

Meriwether Lewis and William Clark began an expedition across the newly acquired Louisiana Purchase territory in the United States. For a little over two years, Lewis and Clark led their corps through some 8,000 mi (12,800 km) of unexplored lands, acquiring scientific samples and creating maps.

1826–63

Johan Heinrich von Thünen, an important theorist in the science of land use, publishes his works, bringing together the fields of economics and geography to provide an illustration of the balance between land cost and transportation costs. Although his system was designed to calculate optimal land distribution in preindustrialized Europe—before the development of railroads, for example—the equations and principles he developed remain the foundation of much of land management practices today, particularly in the developing world.

1844

In Germany, Alexander von Humboldt, Carl Ritter, and Friedrich Ratzel made substantial contributions to human and physical geography. Humboldt's publication *Kosmos* (1844) examines the geology and physical geography of the Earth. This work is considered by many academics to be a milestone contribution to geographic scholarship.

1848

Karl Marx and Friedrich Engels publish the *Communist Manifesto*. The relationship between the middle and working classes, and Marx's views on their association, has been greatly influential in wider social and political thought.

1853

U.S. Commodore Matthew C. Perry ended Japan's isolation when he steamed into Tokyo Bay.

1853

A survey drew the boundary between the U.S. state of Texas and Mexico down the middle of the Rio Grande. The first of a series of disputes came in the wake of floods in 1864, which caused a change in the river's course that left a chunk of 630 acres (about 1 square mi or 1.6 square km) of land north of the river. Several other wanderings resulted in losses or gains of land for both countries in the ensuing years.

1855

A French regional wine-rating system was conceived for the Universal Exposition in Paris, when Bordeaux chateaux ("estates") were ranked along a five-tiered system of *crus* ("growths"). These commercially driven designations later extended to other locales, ultimately coexisting with official French labeling requirements and ratings and marking the advent of the discipline of wine geography.

1859

Charles Darwin publishes *Origin of Species* (1859) and suggests that natural selection determined which individuals would pass on their genetic traits to future generations.

1864

One of the earliest statements of environmental ideas came from George Perkins Marsh in his book *Man in Nature or Physical Geography as Modified by Human Action*. This book is often cited by scholars as the first significant academic contribution to conservation and environmentalism.

1880

The desire to find a shortcut from the Atlantic to the Pacific Ocean stretches back at least 500 years. The reality of construction on a canal began in 1880 when Ferdinand de Lesseps, who oversaw construction of the Suez Canal, gained a concession from the Colombian government, which ruled Panama, to begin work on the canal.

1882

The heads of the various railroads met in St. Louis, Missouri, and worked out a system by which they divided the United States into four standard time zones. Each zone would be centered on a meridian of longitude 15 degrees apart—15 degrees multiplied by 24 hour-wide zones producing the full 360-degree circle of the Earth.

1889

Hans Meyer, a German colonial geographer and rich heir of a huge Leipzig publishing house, first ascended Mt. Kilimanjaro's Kibo crater in 1889 and called it Kaiser-Wilhelm-Spitze (since 1962, Uhuru Peak).

1892

New York City's Ellis Island opened to handle the increasingly large volume of immigrants; in 1907 immigration reached its peak of more than 1.2 million people.

1898

Cuba became independent, and Puerto Rico fell under U.S. administration. The Spanish-American War ended 400 years of Spanish dominion in the Americas and marked the rise of the United States as a world power.

1908

In 1908, U.S. scientist Frank B. Taylor invoked the notion of continental collision to explain the formation of some of the world's mountain ranges.

1911

The environmental determinist movement started with the publication of Ellen Churchill Semple's book (*The Influences of the Geographic Environment*), in which she explained how the environment is considered as a major factor in the location of human settlements and economic activity.

1912

William Davis, among the leading geographers of the early part of the 20th century, retired from Harvard University. Today, Davis might be more narrowly considered a geomorphologist based on his major research interests. But in his time, Davis enjoyed considerable influence over the direction and conduct of geographical science in the United States and in Europe.

1914

With the outbreak of World War I, the Ottoman Empire lined up with the Central Powers and faced a humiliating defeat. After World War I ended in 1918, the empire was under the occupation of several Allied powers, including Britain and Greece. It was not until the Kemalist nationalist movement, named after its leader Mustafa Kemal, famously known as Kemal Atatürk (1881–1938), which ended the foreign occupation of Turkey in 1922, that the Ottoman Empire saw its demise. With the creation of Turkey in 1923,

the oldest imperial power in the world was finally abolished and replaced by a secular republic.

1917

British troops took control of Jerusalem and established the British Mandate in Palestine. In 1949, with the end of the British Mandate, Jerusalem was divided into the New City, the capital of the new state of Israel, and the Old City, under Jordanian control. Jerusalem was unified under Israeli control after the Six Day War in 1967. Palestinians hope to see East Jerusalem as the capital of a Palestinian state. As part of the Oslo Accords in 1993, the fate of East Jerusalem was to be resolved by the Israelis and the Palestinians. However, renewed violence in 2000 has prevented such a settlement.

1917

The ecological niche concept is originated as an attempt to describe the general role of species in the community and to differentiate population, community, and ecological systems. The concept and term was introduced by J. Grinnell, who interpreted it in spatial sense as the ultimate distributional unit of a species. Later C. Elton (1927) concentrated mainly on niche functional aspects when describing an organism's place in its biotic environment in connection with its nutrition and other species.

1920s

A strong rejection of environmental determinism in American geography was led by Carl O. Sauer in the 1920s. For Sauer, the primary purpose of geography should be chorology—or the study of areas. Rather than constrain geographers within the limits of environmental influences, geography should study places in terms of regular characteristics that tied them together.

1929

The environment of the Earth can be broadly divided into four major systems: the atmosphere, hydrosphere, lithosphere, and biosphere. Russian scientist Vladimir Vernadsky coined the term *biosphere* in 1929.

1930s

A number of geographers with political as well as academic interests made political geography an instrument of nationalism. Notable among them were Rudolf Kjellen, a Swede, and Karl Haushofer, a German who was close to Rudolf Hess, Adolf Hitler's deputy in the 1930s. They developed a school of *realpolitik* and

geopolitik, whose writings were used to give an intellectual rationale to 1930s German expansionism—not only the desire to occupy adjacent territories with substantial German populations, such as Austria and Sudetenland, but also Russian areas further east.

Another geographer and politician, Sir Halford Mackinder, whose classic paper related state power to location, led parallel developments in the United Kingdom. In an era when movement of heavy goods and large armies was easier by sea than by land, maritime countries would dominate politically, but as land transport was becoming easier, so land-based powers were becoming stronger.

Mackinder argued that whoever controlled the “world island” (the heartland of Euro-Asia) should be able to control the globe—a geopolitical notion that influenced much strategic thinking throughout the century, until air power (and then power in space) came to dominate military strategy.

1933

Market geography is a subfield of economic geography, which focuses on the spatial nature of market forces. It derives its rationale from the central place theory, first argued in 1933 by German economic geographer Walter Christaller in his book on central places in southern Germany.

1937

Alexander L. Du Toit, a South African geologist, suggested two primordial continents: Laurasia in the north and Gondwanaland (or Gondwana) in the south.

1939–45

World War II marked the first time there was a truly global conflict or war, including Europe, the Americas, Africa, and Asia.

1939

The turn to the study of geographic regions gives birth to the areal differentiation movement in the mid-1930s with Richard Hartshorne’s publication of *The Nature of Geography*.

1947–56

The Dead Sea (the lowest dry point on Earth at 1,292 ft below sea level or -395 m) became famous for the Dead Sea Scrolls, found in eleven caves in nearby Qumran from 1947 to 1956. Literally thousands of Biblical fragments and ancient Jewish documents were found, which added greatly to the understanding of

these religions. Today, the shores of the Dead Sea contain popular beaches, resorts, and spas.

1948

A young meteorological theoretician, Jule Charney, succeeded in deriving simplified mathematical models of the atmosphere’s motions, based on earlier work. The results were dramatic: air flow patterns over North America were accurately forecast 24 hours in advance with greater skill than ever before.

1950s–60s

With few exceptions, the elite—aristocrats, government officials, clergy, and the wealthy—lived in the center of ancient cities, which were usually located near the most important temples. Farther out were the poor, who sometimes huddled along the city walls together. However, the situation reversed in the 20th century, when rings of rich suburbs surrounded most cities and only the poor were left in the city centers. In the United States, the affluent and the middle class who abandoned inner cities populated the suburbs, which grew up around cities in the 1950s and 1960s.

1950

Starting in about 1950, geographic research experienced a shift in methodology. Geographers began adopting a more scientific approach that relied on quantitative techniques. The quantitative revolution was also associated with a change in the way in which geographers studied the Earth and its phenomena.

1952

The European Coal and Steel Community (ECSC) was founded by Germany, France, Italy, the Netherlands, Luxembourg, and Belgium, becoming the predecessor organization to the European Union (EU). The EU included 25 countries by 2004, with many of them adopting the common currency, the euro, to facilitate regional trade and commerce.

1953

The world’s tallest peak, Mt. Everest (29,028 ft or 8,848 m) was climbed by Sir Edmund Hillary and Tenzing Norgay.

1954

The U.S. secretaries of commerce and defense adopted the nautical mile as a means of measurement. It is used in maritime and aerial navigation, in relation to how boat speeds and wind velocities are measured (one

knot is one nautical-mile-per-hour). A nautical mile is approximately one minute of latitude and it used to express distance.

1957

Historian Karl Wittfogel published his book, *Oriental Despotism*, which introduced the concept of water control (hydraulic civilizations) as the basis for the rise and development of civilizations and despotic political systems, from Egypt to China.

1957

The Soviet Union launched the first successful orbiting space capsule, marking the beginning of human use of space for exploration. This led to detailed mapping and monitoring of the Earth's surface, as well as more accurate navigation using global positioning satellites

1960s

Several American scientists, among them Jack E. Oliver and Bryan L. Isacks, integrated the notion of seafloor spreading with that of drifting continents and formulated the basis for plate tectonic theory.

1960s

The widespread introduction of the jet airplane for passenger travel reduced the time needed to reach even the most remote part of the globe. It resulted in massive expansion of business travel and new geographic linkages. Time and distance began to diminish in terms of interaction between once distant places.

1960s–70s

With the advent of the environmental movement in the 1960s, and the subsequent oil crisis and surging energy cost, energy studies became increasingly popular in the 1970s in geography as well as in the general research community.

1960s–70s

This period marked the beginning of the computer age and digital information revolution. Computers and the internet connected the world, regardless of time, distance, or culture: the first example of a global “village.”

1970s

A revival of interests in political geography from the 1970s onward was initially linked to the “quantitative revolution,” which the wider discipline experienced in the 1960s and 1970s. Work on electoral geography started then and geographers increasingly brought

their spatial perspective to bear on a range of subjects broadly defined as “political” and relating in some ways to the operation of the state. Location and conflict (over land uses, public goods, and so forth) became topics considered by political geographers.

1979

The First World Climate Conference made climate change, or global warming, an international issue as it called on all governments to anticipate and prevent human alterations in climate.

1980s

The first commercial geographic information systems (GIS) are developed that relate spatial information to assets, phenomena, or events. A GIS is computerized, and, therefore, is a structured and integrated arrangement of computer hardware, software, and operating procedures and principles designed to support the management of spatial and nonspatial data. These data are collected often via satellite coordinates referenced to the Earth and are maintained in a database.

1983

In *The Fractal Geometry of Nature* (1983), Benoit Mandelbrot writes, “Clouds are not spheres, mountains are not cones, coastlines are not circles, and bark is not smooth.” In an effort to more properly analyze and represent nature mathematically, Mandelbrot developed a new geometric pattern called a fractal.

1995

Again in the news as an international issue, the location of the International Date Line has posed a navigation and time problem since at least the 1700s. In 1995, the line had a minor adjustment so that the new country of Kiribati would be entirely on the same side and the same day, and be the first to mark the new millennium.

1990s

The internet together with a new generation of related computer software and hardware produced a revolution in how we conceptualized and interacted with geographic places and spaces. This revolution was sustained by the continual diffusion of information and communication technology (ICT) into many segments of a globally connected society. These ICT forms include immersive multimedia, video conferencing, computer-aided design, electronic surveillance, consumer profiling, and virtual realities. Virtual geography refers

to the creation of artificial geographies for communication and interaction purposes using concepts from the field of virtual reality (VR).

1991

In August, as Soviet leader Mikhail Gorbachev and his family were vacationing in the Crimea, a cabal of hard-liners staged a coup and held Gorbachev under house arrest. The coup failed because the military refused to carry out the coup leaders' orders. Events continued to spiral out of control as the constituent republics of the Soviet Union clamored for more autonomy and, in the case of the Baltic republics, independence. After an impasse on the relationship between Moscow and the republics, the Soviet Union ceased to exist on December 25, 1991.

1993

The United States, Canada, and Mexico signed the North American Free Trade Agreement (NAFTA), which created a regional free trade zone that lowered tariffs and trading restrictions. NAFTA encouraged greater opportunities for cross-border investments and movement of goods and services among the three countries. The agreement went into effect in 1994.

1996

The Association of American Geographers acknowledged military geography as a subfield of geography and defined it as the application of geographic information, tools, and techniques to solve military problems in peacetime or war. The consideration of terrain, culture, politics, and economics in the pursuit of warfare remains a dynamic field of geographic study and a practical area of military application.

1997

More than 150 nations signed the first legally binding treaty, the Kyoto Protocol, aimed at cutting emissions of the main greenhouse gases believed to contribute to global warming. Later, the United States, under President George W. Bush, declined to participate in the protocol.

1997–98

The El Niño of 1997–98 was one of the worst in recent memory. The weather system caused vast fires in Indonesia and large economic losses impacted many

areas, such as Australia and Southeast Asia, where drought occurred. Ironically, this El Niño came with much advance warning, and heavily populated areas like California were able to invest millions of dollars in preparation, thus avoiding more losses.

Groups such as the National Oceanic and Atmospheric Administration (NOAA) predict and track El Niños using satellites, research ships, buoy arrays, computer modeling, and other tools to analyze ocean temperatures, wind speeds, fish populations, precipitation, and other early indicators of developing weather systems.

2001

The terrorist attacks of September 2001 leveled New York City's landmark World Trade Center towers and killed more than 2,700 people. This was the start of an aggressive U.S. strategy to fight al-Qaeda and other terrorists on a global basis.

2004

Russia ratifies the Kyoto Protocol, the United Nations convention on climate change, which sets limits for the emission of greenhouse gases that contribute to global warming. The United States declines to sign the agreement, citing unfair quota levels for emissions from developed and developing countries.

2016

James Alcock, a professor at Pennsylvania State University, has estimated that at the current rate of destruction, the point of no return in the Amazon rainforest could be reached as early as 2016. Unchecked destruction could entirely wipe out the rainforest by the middle of the 21st century.

2050

It is speculated that one result of the continuing population explosion will be the creation of megalopolises, concentrations of urban centers that may extend scores of miles. It is thought that the first such growth could occur on the East Coast of the United States, where there may eventually be a single urban agglomeration stretching from Boston to Washington, D.C. Other emerging megalopolises include the Tokyo-Osaka-Kyoto complex in Japan, the region between London and the Midland cities in Great Britain, and the Netherlands-central Belgian area.

## abyssal plain

LOCATED IN THE world's oceans, an abyssal plain is a depositional surface on the seafloor. The plain is generally 13,000 to 20,000 ft (4,000 to 6,000 m), extending seaward from the base of a continental slope or from the seaward edge of an oceanic trench to the mid-ocean ridge. The term *plain* implies that this part of the seafloor is a monotonous, uninteresting place. Actually, the plain is remarkable for its sediments, manganese nodules, and life forms.

Much of the abyssal plain consists of tiny particles of brown and red clays, contributed to the ocean by wind deposition and volcanic eruptions. The shells of microscopic marine organisms also make up a significant portion of the sediments. Quiet waters of the deep ocean do not disturb the particles as they accumulate on the ocean floor. Marine scientists study the sediments to glean data about the age of the ocean floor and changes in the ocean's depth, temperature, salinity, and circulation. This information provides clues to geographers and other scientists about millions of years of change in regional and global climate.

Turbidites are distinctive layers of sediments on the edges of abyssal plains next to continental slopes. Turbidites come from river sediment deposited on the outer edge of the continental shelf. Turbidity currents move the sediments from the shelf to the plain. The

currents are slurries of water and suspended sediments. They rush down continental slopes similar to an avalanche, and the resulting turbidites form tongue-like abyssal fans usually near the mouth of a river or submarine canyon.

Turbidites also spread farther out on the plain. They are less abundant in the PACIFIC OCEAN than in the ATLANTIC and INDIAN oceans, because fewer large rivers supply sediments to the Pacific Ocean and its deep-sea trenches trap sediments, preventing their spread to the abyssal plain. Seamounts (submerged mountains) rarely interrupt the abyssal plains of the Atlantic and Indian oceans, as turbidites in these oceans bury most of the mountains. In contrast, many seamounts rise above the abyssal plains in the Pacific Ocean because of a paucity of turbidites there.

These mysterious, potato-size rocks litter the surface. They have thin concentric layers of metals such as iron, cobalt, copper, nickel, and manganese. Chemical reactions in the water add layers that are 0.4 to 8 in (10 to 200 mm) thick every million years. Scientists do not agree on how the nodules form. Some investigators feel that biological productivity in overlying waters control the accretion of metals.

Others argue that the midocean ridge's hydrothermal vents, which exhale such metals from the Earth's interior, are responsible. The metals have aroused interest in the nodules' economic value. Presently, the

nodules are too expensive to mine because of the cost of extracting them from the ocean floor.

The abyssal environment is not conducive to life as we know it; it is perpetually dark and very cold, and the food supply is sparse. Moreover, hydrostatic pressure is enough to crush a person's body to the size of a soccer ball. No plant life exists because of a lack of sunlight. The animals—primarily small worms, crustaceans, and mollusks—are scavengers. They live off bacteria on the seafloor and fecal pellets, bones, carcasses of large animals, and dissolved material that filters down the water column. Population densities are low owing to a harsh environment and scarcity of food.

KUTZTOWN UNIVERSITY

## Aceh

ACEH (full name: Naggroe Aceh Darussalam, meaning “the Abode of Peace”) is one of the three “special territories” among the 27 administrative provinces of INDONESIA. Its location, on the large island of SUMATRA in the northeast corner of the Indonesian archipelago, facing the Andaman Sea and the Straits of Melaka, makes it the closest Indonesian departure point to Mecca, from which it gets the label “veranda of Mecca.” The label is also appropriate on account of the evidence that the Acehnese have the longest history of conversion to Islam in Southeast Asia, dating back to the 9th century, and today as a group represent one of the most staunch adherents of the faith in the region.

Aceh was able to survive as an independent Muslim kingdom since its inception in the early 16th century up to the late 19th century, when it became entangled in a power struggle between British and Dutch colonial interests. Through an Anglo-Dutch treaty in 1824, the British transferred control of some of its possessions to the Dutch, who agreed to allow

the independence of Aceh. In 1871, against the neutral positions taken by the Americans and Europeans, the British allowed the Dutch to invade Aceh, possibly to avert French encroachment in the region, but they were never able to pacify Acehnese resistance, which lasted until World War II. In 1949, the Dutch handed their possessions in the Malay Archipelago to Indonesia, without ever consulting Aceh.

The newly independent Indonesian government immediately dispatched troops to annex Aceh, resulting in widespread resentment of what was viewed as foreign occupation. In 1959, as a way of appeasing the Acehnese, Indonesia conferred on Aceh the status of a “special territory,” allowing a degree of autonomy in matters affecting religion, education, and provincial administration. While this move placated those in favor of a union with the rest of Indonesia, the pro-independent movement remained and subsequently went underground under the name Gerakan Aceh Merdeka (GAM), or Aceh Independence Movement.

In the face of secessionist movements in two other provinces (EAST TIMOR and Papua), the central government declared Aceh as a Military Operations District (Daerah Operasi Militer) in 1989, in a large-scale effort to eliminate GAM. After a decade of oppressive campaigns resulting in nearly 3,000 casualties and the destruction of homes and sources of livelihood, military operations were withdrawn partly in response to worldwide protest and criticism against the Indonesian government.

As of late 2004, the outcome of the Acehnese struggle for independence remains to be seen. The options being deliberated in the media include: continue to fight for outright independence; hold a referendum to allow for popular choice whether to secede or not; or engage in a dialogue with the central government under United Nations auspices to uphold the agreements ratified in the “special territory” status. The most contentious issue concerns the right of the province to enjoy its resources (petroleum and timber).

This “Abode of Peace” was struck by a series of tsunamis, or tidal waves, on December 26, 2004, resulting in more than 100,000 deaths in Aceh and nearby areas of Indonesia. The tsunamis were created by a massive earthquake, registering 9.0 on the Richter scale, in the Indian Ocean. Into 2005, Aceh struggled not only with the issues of independence but also with rebuilding its flood-ravaged territory and economy.

## Aconcagua Mountain

ACONCAGUA MOUNTAIN LIES west of Mendoza, ARGENTINA, entirely within Argentina, and immediately east of Argentina's border with CHILE. The mountain is, at 22,834 ft (6,960 m), not only the tallest mountain in the Western Hemisphere, but also the highest outside of Asia. Its twin peaks, the northern of which is the tallest, can be seen from the coast of Chile 100 mi (162 km) away.

There are different interpretations of the origin of the name *Aconcagua*. It may be derived from the native Quechua *akun* ("summit"), *ka* ("other"), and *agua* ("admired" or "feared"). Thus, it is translated from Quechua as a summit that is feared or admired. Another version is that the name is derived from Arauca roots. Thus, Aconca-Hue is a Mapuche name for the corresponding Aconcagua River that, from Chile, "comes from the other side."

The relatively new mountain was created by subduction of the Nazca plate beneath the South American plate. Geology of the Aconcagua area can be grouped in three basic time periods: a base that developed before the Jurassic period, Mesozoic sequences, and coverings from the Cenozoic period. Glaciers on Aconcagua include Lower Horcones Glacier, the Upper Horcones Glacier, the Los Polacos (or Los Relinchos) Glacier (a climbing route), and the Güssfeldt Glacier. Glaciers on Mount Aconcagua are, owing to more arid conditions, less pronounced than those to the south in Patagonia.

Most of the vegetation and wildlife, because of the aridity and the short growing season at high elevations, are concentrated below 13,123 ft (4,000 m). Typical vegetation is low-growing brush (STEPPE) adapted to low temperatures, thin soils, and high winds. Brush species include *lena amarilla*, *vareta*, and *cuerno de cabra*, with grass species including *buecu* and *coirones*. Wildlife such as the condor, mora eagle, puma, and red fox migrate to lower elevations during winter. Mountain mice hibernate on site. Streams harbor chorlos, churrines, and torrent ducks. Guanacos (similar to lla-

*Aconcagua Mountain in Argentina, at 22,834 ft (6,960 m), is the tallest mountain in the Western Hemisphere.*

mas) can gather in large groups. Hares introduced from Europe are plentiful. Aconcagua Mountain is a provincial park. It was included in 1983 as part of a network of 10 protected areas of the province of Mendoza. It is designated as a Protected Wilderness Area, based on its scenic, recreational, cultural, genetic, and biodiversity values. These areas serve as a reference in relation to similar yet degraded habitats.

General Don José de San Martín crossed the Andes near Aconcagua to liberate the Chilean area from the Spanish in 1817. His army of more than 5,300 men, 9,280 mules, and 1,600 horses crossed at more than 13,123 ft (4,000 m) in elevation. In 1835, Charles Darwin was one of the first European scientists to collect data about the mountain. In January 1985, a remarkable discovery was made by Argentine climbers—an Inca cemetery at 17,388 ft (5,300 m) in elevation. The site included circular stone walls, a mummy, and six statues—three human and three llama figures.

Although the mountain is a large, singular massif, thus nicknamed the "Centinel del Piedra" (Stone Sentinel), various peaks around Aconcagua also surpass 16,404 ft (5,000 m).

Manzur, "Current Situation of Aconcagua," [www.aconcagua.com.ar](http://www.aconcagua.com.ar) (November 2004); R.J. Secor et al., *Aconcagua* (Mountaineers Books, 1999).

WILLIAM FORBES  
UNIVERSITY OF NORTH TEXAS

The Adriatic Sea, between Italy and the Balkan Peninsula, is important for tourism and fishing tuna, sardines, and lobster.

## Adriatic Sea

THE ADRIATIC SEA (in Italian “Mar Adriatico,” in Serbian “Jadransko more”) is a northwest-to-southeast arm of the MEDITERRANEAN SEA. The sea separates the Italian peninsula from the Austro-Hungarian, Montenegrin, and Albanian littorals, and the Italian Apennine Mountains from the Balkan Dinaric Alps. The western coast is Italian and the eastern comprises SLOVENIA, CROATIA, BOSNIA AND HERZEGOVINA, SERBIA AND MONTENEGRO, and ALBANIA. The name derives from the Italian town of Adria (Hadria), designating in early historic times the sea’s upper portion. The term was later extended geographically to the south.

The Adriatic has a total surface area of about 60,000 square mi (160,000 square km), with a maximum length of about 480 mi (770 km) and a width of nearly 100 mi (160 km); however, the Strait of Otranto, connecting the Adriatic and the Ionian Sea to the south, is 45 mi (72 km) in breadth. The mean depth is 133 fathoms (240 m), but the northern portion of

the Adriatic is shallowest between the southern promontory of Istria and Rimini (about 25 fathoms or 46 m), where the low Italian littoral merges in the northwest into marshes and lagoons along the delta of the Po River. The freshwater Po and Adige are the major rivers flowing into the saline Adriatic and account for substantial silting. The Po’s sediment extended the coastline for 2 mi or 3.2 km within the last two millennia.

The area between Šibenik and Ortona (Croatia and ITALY) exceeds 100 fathoms (180 m) in depth, but west of Durrës (Albania) and south of Dubrovnik (Croatia), the basin exceeds 500 fathoms (900 m). The rocky east coast has many long and narrow islands with the long axes lying parallel to the mainland coast and elevations of a few hundred feet; larger islands such as Brac have elevations of 2,552 ft (778 m). There are more than 1,000 islands in the Adriatic, although only 66 are inhabited, notably near Venice (Italy), and Trieste (Italy). Due to eutrophication and minimal tidal flow, making the sea a shallow, closed system, the Adriatic has notable water and air pollution yet remains an important tourism and fishing locale.

## Aegean Sea

THE AEGEAN SEA is an arm of the MEDITERRANEAN SEA, located between the Greek peninsula to the west and TURKEY to the east. The Aegean is connected through the Dardanelles, the Sea of Marmara, and the Bosphorus with the BLACK SEA, while the island of Crete is considered to be the southern boundary. In all, it is about 380 mi (611 km) long and 186 mi (299 km) wide. It has a total area of approximately 83,000 square mi (214,000 square km).

As for the name *Aegean*, there are several explanations: 1) named after the town of Aegae; 2) derived from the queen of the Amazons, Aegea, who died in the sea; and 3) stemmed from Aegeus, the father of Theseus, who drowned himself in the sea when he mis-

takenly thought his son had died in a distant war. The formation of the sea occurred when the Tethys Sea or Seaway began to shrink over the last 120 million years as the approaching African and European plates closed off the Mediterranean and surrounding seas.

During the last Ice Age (2,000,000 to 18,000 B.C.E.), the shallow and narrow Straits of Gibraltar blocked off much of the ATLANTIC OCEAN waters, which led to a saline crisis as a high rate of evaporation in the nearly arid region created a shallow, briny basin. Even today, the generally shallow (average depth of 4,921 ft or 1,500 m) Mediterranean Sea has a low exchange rate with the Atlantic and is saltier. The maximum depth of the Aegean is found east of Crete, where it reaches 3,543 m (11,627 ft). The rocks that make up the floor of the sea are mainly limestone, though proximity to a plate boundary has allowed volcanic activity to alter it.

The Aegean is studded with numerous large and small islands that are the mountain peaks of Aegeis, the name given to a submerged land mass. The Aegean islands can be divided into seven groups: the Thracian Sea group, the East Aegean group, the Northern Sporades, the Cyclades, the Saronic Islands, the Dodecanese, and Crete.

North winds prevail over the Aegean Sea, although periodically, the cold gale-force Bora katabatic drainage wind thunders into the sea from the Balkans. The low tides generally follow those of the eastern Mediterranean. However, the tide of Euripus, the strait between Greece and the island of Euboea, demonstrates a violent and uncertain character, leading to the term the *Euripus Phenomenon*. Cold water masses with fluctuating temperatures flow out of the higher BLACK SEA, impacting the deep waters of the Aegean. The low concentration of phosphates and nitrates, necessary for marine life, limits fishing to sardines and sponges. Likewise, the barren, rocky soil hinders agriculture. Thus, tourism remains the major source of income for the Aegean coastal countries.

Casson, ed., *Essays in Aegean Archaeology* (Books for Libraries Press, 1972); Peter Warren, *The Aegean Civilizations* (Phaidon, 1975); "Tethys Sea," Wikipedia, [www.wikipedia.com](http://www.wikipedia.com) (September 2004); "Aegean Sea Continental Shelf Case," [www.icj-cij.org](http://www.icj-cij.org) (September 2004).

THOMAS M. DEATON  
DALTON STATE COLLEGE

The Aegean Sea lies between Greece and Turkey, bridging the lands of western Europe and the Middle East.

## Afars

THE AFAR PEOPLE live in the rocky desert terrain of eastern Africa, in an area called the HORN OF AFRICA. Most of them live in the countries of DJIBOUTI, ETHIOPIA, and ERITREA. The territory, once known as the French Territory of the Afars and Issas, became Djibouti in 1977, when France gave the people their independence. Although most Afars live in the desert, some live in the Awash Valley and the forests of northern Djibouti. They number about 1.4 million in all. The name *Afar* comes from the first two letters of Africa and Arabia.

The Afars are a cohesive group and did not like having their territory broken up into the countries of Djibouti, Ethiopia, and Eritrea. The Afars in Djibouti are outnumbered by the Issas and were unhappy with the Issa leadership. There was much unrest among the Afars during the 1990s, but a peace accord was finally signed in 2001. Djibouti is important because of its

strategic position at the mouth of the RED SEA. It serves as a port for goods leaving and entering eastern Africa.

Although peace now reigns in Djibouti, the Afars are the target of economic and political discrimination. The Afar people are tall and proud, with narrow, straight noses, thin lips, and small, pointed chins. The Afars are known as fierce fighters. They have managed to survive under the worst conditions in one of the hottest areas in the world. The Issas are their main enemies. A man is judged on his bravery and strength among the Afars.

The Afars subsist mostly on a diet of bread and milk, and many are malnourished. They are often anemic and are prone to malaria because of their poor diets. Historically a pastoral people, over half of the Afars live a nomadic life, moving their livestock wherever they can find grazing. They raise sheep, goats, camels, and cattle. Rainfall is sparse in the area, so the people are forced to move often in search of grass for their animals. Both droughts and floods have had a negative effect on the economy of the Afars. Some Afars living along the Red Sea fish for a living. The Afars have also mined salt for many years and export it to Ethiopia.

Most Afars embrace the Muslim religion, which differentiates them from other tribes in the area that are Christian. Muslim practices are supplemented with ancient animist customs as well.

## Afghanistan

**Map Page** 1123 **Area** 250,000 square mi (647,500 square km) **Population** 28,717,213 **Capital** Kabul **Highest Point** 24,550 ft (7,485 m) **Lowest Point** 846 ft (258 m) **GDP per capita** \$700 **Primary Natural Resources** natural gas, petroleum.

THE STATE OF AFGHANISTAN is a landlocked country that borders PAKISTAN to the south, IRAN to the west, TURKMENISTAN, UZBEKISTAN, and TAJIKISTAN to the north, and CHINA to the northeast. The country is divided into 32 provinces. Since the overthrow of the Taliban in 2001, Afghanistan is in the process of reconstructing its government.

Afghanistan, known since ancient times for its lapis mines, is divided by several mountain ranges. Cutting the country in half is the HINDU KUSH, from which smaller ranges project: from the Band-I-Turkestan on the west to the Suleiman Range to the east. To the southeast is the Dasht-I-Margo desert. Afghanistan has a dry climate with hot summers and cold winters. The country experiences sparse rainfall. Its chief rivers are the AMU DARYA, the Kabul, the Helmand, and the Hari Rud. Major cities include Kabul, Kandahar, Herat, Mazar e-Sharif, Jalalabad, and Konduz.

### ANCIENT LANDS

The region in and around Afghanistan has been inhabited since the Paleolithic and Neolithic eras. Afghanistan has been the scene of migrations throughout history. Since ancient times, Afghanistan captured the interest of foreign peoples. The region of what is now Afghanistan entered into recorded history under the PERSIAN EMPIRE. By 331 B.C.E., Alexander the Great extended his empire into Afghanistan after conquering Persia. Alexander's empire disintegrated after his death in 323 B.C.E. with Afghanistan passing to Seleucis Nikator, one of his generals. Afghanistan soon after came under the control of Chandragupta from INDIA. Around 650 C.E., ISLAM came to Afghanistan through Arabs who conquered the Sassanids in Persia. In 1219, the Mongols under Genghis Khan spread destruction throughout Afghanistan. For 500 years, Afghanistan was part of the power plays between the Mughals in India and the Safavids in Persia. In the 18th century, Afghanistan was united for the first time under Ahmed Shah Durrani, who created an empire that included modern-day Pakistan.

By the 19th century, Afghanistan was caught in the middle of the imperial ambitions of Britain, which had controlling interests in India and RUSSIA. Britain fought two wars to gain control of Afghanistan, both of which ended disastrously. In the 20th century, Afghanistan entered a period of modernization through King Amanullah between 1919 and 1929. In 1933, King Mohammad Zahir Shah extended the modernization through the creation of a constitution and a parliament. However, by the 1960s, the communists had

gained a foothold in Afghan politics, and by 1973, Sardar Mohammad Daoud abolished the monarchy and established a republic with financial backing from the Soviet Union.

In 1979, the Soviet Union invaded Afghanistan to support a communist government under the Najibullah regime. Soviet occupation was met by fierce resistance by the Mujahideen, who were mainly supported by the United States. In 1989, the Soviets withdrew from Afghanistan, prompting civil war among the Mujahideen. By 1996, Afghanistan fell under the rule of the Taliban, a fanatical extremist Muslim sect. The Taliban imposed Sharia law as the legal system for Afghanistan and severely restricted women's rights. Additionally, Afghanistan became a breeding ground for international terrorism, harboring Osama bin Laden, leader of the al Qaeda terrorist group that masterminded the attacks in New York City and Washington, D.C., on September 11, 2001.

In November of that year, the United States led a coalition of nations to overthrow the Taliban regime, when it would not surrender bin Laden. The Taliban offered no significant resistance and retreated to the mountains. At the end of 2001, an agreement was reached in Bonn, Germany, to lay out a blueprint for Afghanistan's reconstruction.

Afghanistan has a diverse array of ethnic groups. The Pashtun are the majority ethnic group, followed by Tajiks, Uzbeks, Hazara, Aimaq, Turkmen, Baluch, and Nuristani. Pashto and Dari are the main languages spoken. Twenty years of war have left Afghanistan's infrastructure in ruins. Agriculture makes up 60 percent of the economy. Afghanistan is one of the leading exporters of opium, which is most profitable for farmers to grow.

## Agricultural Revolution

AROUND 11,000 B.C.E., human beings began to domesticate and cultivate plants. This new activity, which eventually changed populations, lifestyles, and the en-

vironment in profound ways, proceeded in sporadic bouts. Although the development of agriculture took place over millennia on different continents, its initial beginning is sometimes referred to as the Agricultural Revolution.

Archaeological evidence shows that men and women began cultivating grains between 12,000 B.C.E. and 10,000 B.C.E. in the Middle East. Sites in the ZAGROS MOUNTAINS of IRAN, TURKEY, SYRIA, and the Jordan River Valley, collectively known as the FERTILE CRESCENT, all indicate that cereal grains were first deliberately grown there by farmers. This region contains over 50 archaeological sites from 8,000 to 10,000 years old, all giving evidence that agriculture was practiced. Specifically, the earliest sites found are along the Levant Corridor, which runs south from the mid-Euphrates River valley to the lower Jordan River valley. The Natufian complex of the Levant provides archaeological evidence of farming villages that date from 10,500 B.C.E. While the cereal grains harvested there were still considered wild, they may have been planted intentionally, in plots cleared for the seeds. The Natufians, living in what is now northern ISRAEL and Jordan and southwest Syria, established permanent homes, stored food in stone jars, and used grindstones, mortars, and pestles to process grain.

Farming is more labor-intensive than hunting and gathering; the motivation for changing from one lifestyle to the other is not known. Climate changes and glacial retreats in the previous millennia may have led to increased yields of wild plants. Hunters and gatherers, noticing the increase, may have developed cutting tools and storage facilities to take advantage of the abundance of grain.

Other factors that may have prompted the switch to sedentary farming include the decline of at least one animal, the wild gazelle, which had been a significant food source in the Fertile Crescent. Research scientists have also put forth population expansion and the social pressure upon village leaders to provide feasts as possible explanations for the development of local agriculture.

### EARLY FARMERS

The harvesting and selection methods of early gatherers, who eventually became farmers, changed growth patterns and made domesticated plants different from their wild varieties. Larger and sweeter fruits, peas, and legumes were eaten more often, and their seeds were the ones collected and germinated. In the case of wheat, only stalks on which the seeds stuck to the stalk

were collected by people, and thus cultivated wheat came from these seeds and is easily identifiable. The stalks of wild wheat tend to break and scatter their seeds on the ground.

Archaeologists use radiocarbon dating on plant material; by plotting where the earliest domesticated plants are found, they can chart the spread of cultivation. As an example, remains of ancient, wild varieties of emmer wheat are found in Israel, Turkey, and Iran. Emmer wheat was the most common cultivated grain. The earliest example of domesticated emmer wheat was found in the Fertile Crescent area and dates from 8500 B.C.E. The earliest instances found of this crop in Europe date from 6800 B.C.E. in GREECE, then 6000 B.C.E. in GERMANY. Advances in radiocarbon dating over the last two decades have led to corrections in previously published dates and confusion in books.

Emmer wheat, einkorn wheat, and barley were domesticated by 8000 B.C.E. in the Levant, and within three centuries the people of this region were intentionally sowing all their wheat from stored seed. The wild variety of these three grains was no longer being consumed. Also by 8000 B.C.E., cereals were being introduced in areas where they had not previously grown wild, and farmers were selecting seeds for qualities that would increase crop yield.

From this area, agriculture spread both east and west. The similar climates and lack of insurmountable boundaries in those directions allowed this. Agriculture reached eastern Europe and EGYPT by 6000 B.C.E., and spread to western Europe, North Africa, INDIA and southern Asia by 3000 B.C.E. The sharing of new cultivation techniques to the north and south, however, was impeded by differences in weather such as extremes of cold and lack of sufficient rain. The eight major crops, called founder crops, developed in the Fertile Crescent during the Agricultural Revolution were emmer wheat, einkorn wheat, barley, lentils, peas, chickpeas, bitter vetch, and flax—which produces both oil and the fabric linen.

Rice and millet were cultivated in river valleys of CHINA, starting from 6500 to 5500 B.C.E. In the Americas, the earliest evidence of cultivation dates to 4000 B.C.E. and is found in the lowlands of northern South America. There is evidence of cultivation in New Guinea dating to 7000 B.C.E. Sub-Saharan Africa developed agriculture by 2000 B.C.E., as did some areas of eastern North America and Central America. In pointing to these independent developments, though, it is important to remember that the archaeological evidence is sparse, scattered, and often hit-and-miss. Im-

portant sites bearing new data may have been destroyed over the years or have not been discovered.

Agriculture changed the landscape, wherever it was implemented. Fields, plowed and uprooted of their native, variegated plant species and forced to grow only one particular plant, became depleted of some nutrients and inhospitable to certain animals and insects that lived there in the past. Other animals that could live on the cultivated plants were therefore favored and become more numerous.

### ANIMAL DOMESTICATION

The domestication of animals often occurred in conjunction with the domestication of plants, since the latter led to permanent settlements in which herds of animals would be penned in to ensure a food source. As early as 9000 B.C.E., sheep were being bred and domesticated in the ZAGROS MOUNTAINS. Cattle were domesticated in the area by 6000 B.C.E.

Before men and women farmed, they had to travel from place to place, and from season to season, finding their food where it grew wild. People did this for thousands of years. Being able to control food production, and to store or sell excess crops, meant that families had to stay with their fields and land. They built permanent homes and storage facilities. Villages grew, and over many generations, the specialization of labor developed. Those who farmed could sell food to those who performed other tasks: the stonemasons, carpenters, weavers of cloth, and so on.

Since excess food, cleverly traded, could lead to wealth and power, a stratified political and economic class rose, probably over generations—perhaps even over centuries. Food and wealth had to be protected, so means to ensure social control became part of life. Large communities of people meant strength in numbers and led to military conquests and aggression. The famous, protective walls of Jericho, where wheat, barley, and figs were cultivated, were constructed around 8000 B.C.E.

There were clear disadvantages and threats inherent in the agrarian lifestyle. Larger and larger communities became dependent upon fewer varieties of food and vulnerable to shortages caused by droughts or variations in weather, as well as pests and diseases. Famine and starvation were constant threats. Also, populations grew more rapidly when they became settled and permanent. Mothers in hunter-gatherer groups limited births because the group needed to be mobile to survive; too many infants to carry would slow it down. In a farming society, however, mothers

tended to have more babies, closely spaced. Because surplus food facilitates population growth, more and more food needed to be grown. These are problems that continue to affect all areas of the world.

## Ahaggar Mountains

THE AHAGGAR IS a large mountainous plateau region lying on the TROPIC OF CANCER in the north-central SAHARA DESERT. It covers an area of 210,000 square mi (543,900 square km) which is about the size of FRANCE, or of ARIZONA and NEW MEXICO combined. It is about 1,000 mi (1,609 km) east of the ATLANTIC OCEAN, 1,000 mi north of the BIGHT OF BENIN, and 1,000 mi south of the MEDITERRANEAN SEA.

Most of the Ahaggar lies in southeast ALGERIA about 900 mi (1,450 km) south of Algiers. However, small areas extend into NIGER in the south and LIBYA in the northeast. The Ahaggar is a part of the Mid-Sahara Rise, which stretches 1,300 mi (2,092 km) east to west and 965 mi (1,553 km) south to north. The Mid-Sahara Rise includes the Adrar des Iforhas Mountains in MALI and the Massif de l'Air Mountains in Niger.

The Sahara lies on the African shield, a thick pre-Cambrian crystalline base. Geological studies have concluded that about 300 million years ago violent earthquakes of enormous proportions pushed up this central massif or plateau region of the Sahara. This was followed by volcanic eruptions that poured enormous beds of basaltic lava over the area.

The geologic activity underlying the Ahaggar plateau pushed its granite base up thousands of feet above the Sahara. The Ahaggar plateau's height is

above 3,000 ft (915 m). The geologic activity produced enormous cliffs and fissures. These were broken into strange formations. At the heart of the Ahaggar, volcanic eruptions produced pumice and lava beds in many areas, some of which are basaltic. There are also "organ pipes" or volcanic needles or spires of rock that may reach 1,000 ft (305 m) high.

The Ahaggar Mountain chain, which is also called the Hoggar Mountains, is situated on top of the Ahaggar plateau. The plateau is like a platform covered with lava fields. The Tuaregs call the platform the Atakor, while the Arabs call it the Kudia. The Atakor platform averages 6,600 ft (2,012 m). At the heart of the Ahaggar chain is the Atakor range, which has extinct volcanoes in many places that rise to about 9,000 ft (2,743 m). They rise from the plateau and are the highest portion of the plateau. At the center of the Ahaggar Mountains is the highest peak, Mount Tahat (9,573 feet or 2,918 m). Other peaks include Mount Atakor and Mount Assekrem, which is where the Berber Tuaregs locate the "end of the world."

While most of the Ahaggar is waterless and totally bare of vegetation, there are occasional snows. In some places in deep ravines, there are verdant strips that can be seen on aerial photographs. There are two waterfalls in the Ahaggar. One is at Tamekrest and the other is at Imeleoulaouene. A variety of animals live in the mountains along with the nomads, mostly Tuaregs, who frequent the oases located in these rugged reaches.

DALTON STATE COLLEGE

## Alabama

THE HEART OF THE Confederate States of America during the Civil War, much of the state of Alabama was originally part of GEORGIA, its eastern neighbor in the south-central UNITED STATES. The British and French fought over the southernmost area until it was ceded to

the British in the War of 1812. Scholars disagree on whether the state was named for the Alabama River or the Alibamon Indians who resided in the area during the period of the Creek Confederacy. Alabama is bounded on the east by Georgia and the Chattahoochee River, on the west by MISSISSIPPI, on the north by TENNESSEE, and on the south by FLORIDA and the ATLANTIC OCEAN.

Alabama encompasses 52,423 square mi (135,774 square km), ranking 30th in size among American states. The largest cities are: Birmingham, Montgomery (the capital), Mobile, Huntsville, Tuscaloosa, Dothan, Decatur, Auburn, and Gadsden. Alabama's major rivers are the Mobile, Tombigbee, Alabama, Tennessee, Chattahoochee, and the Tensaw. The largest lakes in the state are Guntersville, Wilson, Martin, West Point, and Lewis Smith.

While the coastal area of Alabama boasts a subtropical climate, the climate in most of the state is temperate with average temperature ranges from 91.5 degrees F (33 degrees C) in the summer to 30 degrees F (-1 degree C) in the winter. While rain falls throughout the year, most of the state rarely sees snow. The average rainfall for the state is 53 in (134 cm). The average elevation of the state is 500 ft (152 m) above sea level. The highest point in the state is located at Cheaha Mountain, "high place," 2,407 ft (734 m) above sea level. The lowest elevation in the state is where the land meets the sea in the Gulf of Mexico.

Russell Cave near Bridgeport provided a haven for Native Americans from 6000 B.C.E. to 1650 C.E. The cave, which is now cared for by the National Park Service, provides a first-hand look at the tools, weapons, and the day-to-day lives of Native Americans. Moundville Campgrounds near Tuscaloosa has also preserved vestiges of Native American life.

The terrain of Alabama ranges from the coastal plains in the southern part of the state near the Gulf of Mexico to the rugged terrain of the northern section of land where Alabama merges into Tennessee. Alabama is made up of five major land areas: the East Gulf Coastal Plain, which covers roughly two-thirds of the state, excluding the section known as the Black Belt Prairie, where many plantations were located during the antebellum period; the Piedmont Upland found in the central section of Alabama, which is made up of low hills and sandy valleys; the Appalachian Ridge and Valley, which is made up of sandstone ridges and limestone valleys; the Cumberland Plateau, also known as the Appalachian Plateau, which is made up of varying sections of rolling hills and flat areas; and the Highland

Rim in the northwest corner of the state, which makes up part of the Tennessee River Valley. The section of the East Gulf Coastal Plain around Mobile, which is the state's largest seaport, is low and swampy. In the plains of southeastern Alabama, known as the wire-grass section, the soil is the most fertile within the state. Farming flourishes in this section with its fertile soil and easy water access. Waterfalls and caverns are found throughout the mountainous area of north Alabama.

Until the beginning of the 21st century when manufacturing, government, and services began to dominate the economy, Alabama's productivity was largely dependent on farming. Alabama's economy continues to benefit from the production of farm products that include cotton, peanuts, corn, and hay. Chicken, cattle, dairy products, and hogs provide the majority of the state's livestock exports. Top manufacturing products include textiles, fabricated metal products, transportation, paper, food, chemicals, plastics and rubber, and wood.

Approximately two-thirds of Alabama is forested, and the state is home to more than 125 varieties of trees and more than 150 species of shrubs. Alabama's trees include pines, oak, hickory, cypress, and southern magnolia. Shrub varieties include rhododendron, mountain laurel, azalea, and sumac. Animals found throughout the state include white-tailed deer, red fox, squirrel, muskrat, nutria, beaver, and rabbit. Game birds include ducks, geese, and quail, while the state's most common songbirds are the yellowhammer, bluebird, cardinal, blue jay, and mockingbird. Minerals found in the state include coal, iron ore, petroleum, natural gas, limestone, gravel, bauxite, and clay.

ELIZABETH PURDY, PH.D.  
INDEPENDENT SCHOLAR

## Alaska

THE 49th STATE admitted to the union in U.S. history, Alaska is located northwest of the 48 contiguous states. It borders CANADA to the east, the PACIFIC OCEAN to the south, the Bering Sea to the west, and the ARCTIC

OCEAN to the north. Alaska has several distinct physical regions. The southernmost region is named the Pacific Mountain System. The panhandle in the southeast mainly comprises the Alexander Archipalego, while south-central Alaska is made up of the Alaska Range, home to Mount MCKINLEY, or Denali, the highest point in North America at 20,320 ft (6,194 m). The coastal part of this region includes Prince William Sound and Cook Inlet. Lying southwest of the Alaska Range are the Alaska Peninsula and the ALEUTIAN ISLANDS.

To the north of the Alaska Range, up to the Brooks Range, are low hill and valleys, or the Central Uplands and Lowlands. To the west are Alaska's main river valleys (the state's major river is the Yukon, flowing approximately 1,979 mi or 3,185 km) and to the north lies the state's vast treeless tundra.

America's northern state has a rich and diverse past. Before becoming a Russian colony in the 18th century, the land was populated by some 70,000 natives, living in the the interior and southeast portion of the area. Here, the Tlingit and Haidi tracked caribou and fished. The Aleuts who inhabited the outer Alaska Peninsula hunted seals, sea lions, and whales. And the Yupik and Inupiaq Eskimos lived in harsher conditions while hunting for caribou, seal, walrus, and fish.

In the 1740s, Russian fur-trading companies arrived on the Alaskan panhandle, and the way of life for the Aleuts was adversely affected. In 1778, the British explorer Captain James Cook visited the area, and a fur "rush" began. By the end of the century, British, Russians, and Americans were hunting in this newly formed Russian colony, governed by Aleksandr Baranov.

The Russian colony, however, posed many problems for the Russian government. The distance from the Russian capital of St. Petersburg was difficult to overcome and food shortages were prevalent. The Russian settlements in northern CALIFORNIA were also failing as grain suppliers. In 1867, Russia sold its colony of Alaska to the United States for around two cents an acre. Many Americans questioned the deal and thus named the purchase "Seward's Folly," after William H. Seward, the U.S. secretary of state who negotiated the deal.

For the remaining period of the 19th century, the Alaskan territory failed to attract farmers. However, many speculators became involved in the whaling industry, and the Gulf of Alaska turned into a haven for salmon fishing. Between 1878 and 1899, mainly because of Alaska, American canned salmon exports grew significantly. In 1896, gold was discovered in the

Klondike River claim in Canada's Yukon territory, near the border with Alaska. Gold prospectors soon traveled north and traveled through Alaska, and many prospected in Alaskan gold claims. Coastal towns such as Valdez and Juneau (the capital) were created. The gold rush lasted for over a decade, but by World War I, speculators began to dwindle across the territory. In the 1920s, Alaska's white population primarily gathered along main transportation routes and in certain mining areas.

The scene was virtually unchanged until the outbreak of World War II, which witnessed American military personnel being sent to bases in the area. By 1943, 124,000 military personnel inhabited Alaska, and fortifications were created in defense of the Japanese. The Alaska Highway was also finished during this period, which linked Alaska to Canadian railroads. The military remained in Alaska after the war, as part of the distance early-warning (DEW) radar stations to defend against possible Soviet missiles during the Cold War.

### ALASKAN OIL

In 1959, Alaska achieved statehood. In 1968, an arctic oil field was found at Prudhoe Bay, and three years later, the Alaska Native Claims Settlement Act was negotiated, which set up the creation of the trans-Alaska pipeline. The U.S. government gave 44 million acres (18 million hectares) and \$962.5 million to the indigenous people.

In return, the native Alaskans forfeited their rights to make aboriginal land claims. Thirteen regional and

*A glacier in Alaska's Prince William Sound, where oil transport continues to endanger the natural habitat.*

around 200 village corporations have thus invested in oil drilling and other Alaskan industries. All of the native Alaskans are individual shareholders in these companies.

The pipeline from Prudhoe Bay to Valdez was constructed in the mid-1970s and resulted in incredible population increases to Fairbanks and Valdez. In the 2000s, oil money accounts for almost 80 percent of the state budget, and Alaska has become the United States' largest oil-producing state. The money from the oil business has improved education, transportation, medical care, and communications.

Overall, Alaska has the highest average household income in the country. However, the effects of oil production continues to be debated across the state, especially after the *Exxon Valdez* oil spill, which affected Prince William Sound in 1989. This catastrophic oil spill of 10 million gallons damaged the ecosystem throughout the polluted area. In the early 2000s, debate centered on whether oil drilling should be conducted in the Arctic National Wildlife Refuge in the remote northeast corner of Alaska.

## Albania

**Map Page** 1133 **Area** 10,685 square mi (28,748 square km) **Capital** Tirana **Population** 3,582,205 **Highest Point** Maja e Korabit 9,085 ft (2,753 m) **Lowest Point** 0 m **GDP per capita** \$4,500 **Primary Natural Resources** petroleum, hydropower.

ALBANIA IS UNIQUE in many ways. This small, mountainous nation on the western side of the Balkan Peninsula has a language and a culture that differ significantly from those of its neighbors. Most notably, it

is the only country in Europe with a majority Muslim population. Albania has been isolated from the outside world for most of its history, at first because of the physical inaccessibility of its terrain and later because of 500 years of occupation by the OTTOMAN EMPIRE.

### ISOLATION

Even during the period of communist rule after World War II, Albanian leaders pursued their own individual course in spite of pressure from its larger neighbors in Yugoslavia and the Soviet Union, resulting in one of the most isolated nations in the world—politically, economically, and culturally. Since reforms began in 1990, Albania has struggled to catch up to the rest of Europe, lagging far behind in political and economic development.

Almost all of Albania is mountainous, from the southern reaches of the Dinaric Alps in the north to the various smaller ranges to the east and south. These ranges form Albania's borders: SERBIA AND MONTENEGRO to the north, MACEDONIA (Former Yugoslav Republic of Macedonia) to the east, and GREECE to the south. Many Albanians live across these borders, however, principally in the province of Kosovo to the northeast, but also in Macedonia and Greece. The numbers of Albanians living in these regions is frequently debated and is the cause of regional tensions, as Albanians seek to find a unified voice for themselves throughout the Balkans.

The narrow coastal plain along the ADRIATIC SEA is the site of Albania's limited agricultural output, raising products suitable to a warm Mediterranean climate: citrus, figs, grapes, olives. The plain is watered by Albania's major rivers, the Drin, Ersenn, and Semani. Higher elevations are suitable for growing wheat and for tending sheep and goats. The mountains also contain mineral wealth, but Albania lacks the resources to extract them profitably. Where the mountains meet this plain is where most of Albania's larger towns are located, including the capital, Tirana, at the foot of the Dajti Mountains. The other major cities are Shkodra in the far north, Durrës on the coast, and Vlora in the far south, where the mountains come right down to the sea. These latter three cities, long important for trade in the Adriatic, were Venetian merchant republics for much of their history, reflected in their historic names, Scutari, Durazzo, and Valona.

Today, most Italian influences are gone, and these cities are repopulated with ethnic Albanians, a people whose origins are unclear, but who are believed to be the region's oldest inhabitants, predating the neighbor-

ing Slavic peoples by several centuries. Their language is believed to be derived from that of the ancient Illyrians, a people whose kingdoms once dominated the Balkan Peninsula until they were conquered by the Romans in the 1st century B.C.E., then pushed out of much of their original territory by migrating Slavs in the 6th to 8th centuries. A medieval kingdom was resurrected in the 15th century under Albania's principal national hero, Skanderbeg, winning a notable victory over the Ottoman Turks in 1449. But within 40 years, Albania had fallen to the Ottomans and had to wait until 1913 to recover its political independence.

In the meantime, Albania became the only European province of the Ottoman Empire in which the majority of its inhabitants converted to Islam, and Albania contributed significantly to the development of the Ottoman state—several of its sons rose through the ranks to become grand vizier, chief minister of the sultan. After gaining independence, Albania veered from republic to monarchy and back before submitting entirely to the strict socialist regime led for four decades by Enver Hoxha. During this period, Albania's economy was 100 percent nationalized (even personal cars were owned by the state), and diplomatic ties were cut with all of its former allies, Yugoslavia, the Soviet Union, and finally, even CHINA, leaving Hoxha's regime completely isolated.

Since 1992, a new regime and a new constitution have attempted to reverse the mistakes of the past fifty years, but Albania remains the least developed country in Europe, with about half of its population working on small farms and half of its industry shut down. Today, much of the national income derives from remittances sent back from Albanians working abroad, mostly in Greece and ITALY.

## Aleutian Islands

KNOWN AS THE Catherine Archipelago until 1900, the Aleutian Islands comprise some 150 islands in four

Part of Alaska, the Aleutian Islands are America's northwest frontier, populated by native Aleuts.

groups, which are, in order of proximity to the mainland: the Fox, Andreanof, Rat, and Near Islands. The name probably derives from the Chukchi word *aliat*, meaning "island." Geographically, the islands separate the Bering Sea from the PACIFIC OCEAN. They extend in an arc about 1,600 mi (2,560 km) into the Bering Sea off the west coast of ALASKA, to which they belong politically. Their total area is 6,821 square mi (17,666 square km) and the total population is approximately 12,050.

Geologically, the islands comprise limited sedimentary and metamorphic rocks but are mainly volcanic in origin and are located at the junction between the Pacific and North American tectonic plates. They are characterized by volcanic peaks representing a continuation of the Aleutian range of mainland Alaska. Some volcanic peaks remain active, including Makushin on Unalaska and Shishaldin on Unimak, which are the largest islands in the Fox group.

Climatically, the Aleutians are oceanic, with annual temperatures ranging on average from 30 degrees F (–1 degrees C) in January to 52 degrees F (11 degrees C) in August. There is a 135-day growing season between May and September and annual rainfall is 80 in (2.03 m) with rain occurring all year with abundant fog. The natural vegetation is a mixture of Asian and American species comprising dwarf shrubs with grass-, sedge-,

and herb-rich meadows in the lowlands and mosses, lichens, and alpine herbs in the uplands. Most of the islands are within the Aleutian Biosphere Reserve and Wildlife Refuge, which contains a unique mixture of marine birds and mammals.

The islands were colonized at least 8,000 years ago by hunter-gatherers migrating east from Asia when sea levels were considerably lower than today. The native people, the Ungangans, encountered by European explorers in the 1700s were named Aleuts. In 1741, the first European arrivals were Vitus Bering, a Danish seafarer in Russian employ, and Alexei Chirikov; they captained separate ships and each discovered different islands. Bering was shipwrecked and died on what is now called Bering Island in the adjacent Russian-owned Komandorski Islands.

Thereafter, Siberian fur trappers established bases as Russia extended its influence in North America, leading to the exploitation of the Aleuts for labor and the large seal and otter populations for furs. That ended with the transfer of Alaska to the United States in 1867. Further development came with the discovery of gold in Nome in 1900 and the establishment of Dutch Harbor, Unalaska, as a shipping port.

### JAPANESE OCCUPATION

During World War II, the Aleutian Islands featured in hostilities between the United States and Japan. A naval base was constructed at Dutch Harbor in 1942, and following its bombing, the Japanese occupied several islands but were routed in 1943 by U.S. forces from bases on other islands. Underground nuclear tests were carried out on Amchitka (Rat group) in the 1960s and early warning radar systems, pointing toward Soviet Russia, were constructed during the height of the Cold War.

Today, sheep and reindeer herding are part of the economy, with some production of market garden commodities. Hunter-gatherer traditions involving hunting and fishing equipment, including basketry, are maintained by modern-day Aleuts. Fishing and hunting of seal are overseen by the federal government and only Aleuts are allowed to undertake such activities.

## Algeria

**Map Page** 1113 **Area** 1,479,945 square mi (2,381,740 square km) **Population** 32,277,942 **Capital** Algiers **Highest Point** 9,852 ft (3,003 m) **Lowest Point** -131 ft (-40 m) **GDP per capita** \$5,600 **Primary Natural Resources** petroleum and natural gas, mining.

WITH MORE THAN 80 percent of its land covered by the SAHARA DESERT in northern Africa, Algeria is a country with a history of trade, faith, and conflict. Bordered to the north by the MEDITERRANEAN SEA, Algeria lies between MOROCCO to the west and TUNISIA to the east. Occupying a geographic area of 919,595 square mi (2,381,740 square km), Algeria is the second-largest country in Africa, after SUDAN.

Dominated by the Sahara, Algeria is mostly high plateau with some mountains and a narrow coastal plain along the Mediterranean that has played a major role in the region's history. Strategic Roman outposts dotted Algeria's coast until Emperor Trajan (19–117 C.E.) spread his legions building distant desert cities like Thamugadi (Timgad) and Cuicul (Djemila); these imposing ruins still stand amid sand dunes and oil rigs. However, commanding these Roman settlements was not easy: Native Berber resistance to their presence was constant.

Algeria's Roman cities not only secured Roman involvement in the regional political theater, but also produced some of the Mediterranean's most distinguished personalities, including Saint Augustine of Hippo (354–430), one of Christianity's most notable theologians. Later besieged by Vandals in 429, followed by Byzantine troops 100 years later, Algeria has been a battlefield for citizenry against intruders for more than 2,000 years.

### POPULATION GEOGRAPHY

Algeria's earliest inhabitants were Berbers who remained in the mountainous regions through Roman, Vandal, and Byzantine raids and colonization. Even during Arab expansion and the spread of Islam during the 7th century, the Berbers managed to stay distant, preserving much of their culture, and to this day they represent 30 percent of Algeria's population and a growing voice throughout the country. After Arab, Ottoman Turk, and Spanish influence, the French con-

quered Algeria in 1830. This protectorate of France endured cultural concession, oppression and compromise until the struggle for independence began in 1954. Fomented by the National Liberation Front (FLN), Algeria gained its political freedom eight long years later in 1962.

Since the late 1980s, Algerian politics have been managed by a discomfiting antagonism between military and Islamic militants. In 1992, a victory by the Islamist Party was rescinded, setting off bloodshed that killed thousands of citizens. Only after national amnesty was declared were the weapons laid down on both sides.

After political instability and the natural death of President Boumediene in 1980, his closest friend and minister of foreign affairs, Abedlaziz Bouteflika, was forced into exile, only to return eight years later to work with the FLN Congress. In 1999, he was elected president and reelected in 2004. In 2002, after months of unrest among the Berber communities, the government recognized Berber as an official language, shaping a new focus on its unique culture and history.

Though the country is nearly 10 times the size of CALIFORNIA, Algeria's narrow Mediterranean coast is today home to most of the activity: cities, farms, ports, and highways. With a lucrative export trade overshadowing its low import levels, Algeria's industrial sector has been strong since oil was discovered in 1956. Algeria's extensive supplies now rank worldwide as fifth in gas reserves and 14th in oil, which have dramatically increased the gross domestic product. Oil and gas wells are primarily located inland, with an extensive pipeline network feeding the ports of Arzew and Skikda. Petroleum, petrochemicals, and natural gas are Algeria's largest exports.

## alluvial fan

THE U.S. COMMITTEE on Alluvial Fan Flooding recently defined an alluvial fan as “a sedimentary deposit located at a topographic break, such as the base of a

mountain, escarpment, or valley side, that is composed of streamflow and/or debris flow sediments and that has the shape of a fan either fully or partially extended.”

The fanned or delta shape of alluvial deposits from mountains is formed over many thousands of years by downward-flowing waters or mud leaving the confines of their channel and spreading out into a wider area. The increase in the width of flow causes a decrease in the depth and velocity of the rushing water, which allows the deposition of sediment. This sediment consists of sand, debris, clay, and gravel carried by the stream or river from higher elevations, which can spread over hundreds of miles or kilometers.

Erosion also plays a part in alluvial fan formation, as newer flows carry away or redistribute material deposited earlier. Fans that sit inactive through climate changes and tectonic activity over many centuries are also subject to weathering and wind erosion. Alluvial fans are built unevenly; varying amounts and size of debris, volume of water, and placement of previous deposits influence where the alluvium is left. Usually, the larger rocks are closest to the topographic break, while finer grains travel further before being deposited. Some areas of the fan build up more sediment than others over years. Overall, the slope of a fan is commonly under 10 degrees. A flash flood leaves a different pattern of deposits than a shallower and less violent stream of water. Alluvial fans can consist of evenly dropped sand or be riddled with channels and trenches of varying depths. The former is considered more dangerous, because the lack of paths for water makes predicting the pattern of future floods impossible.

Alluvial fans are most often found at the base of hills and mountains in arid or desert environments or piedmont plains all over the world. They are very common in western North America; in PAKISTAN, IRAN, and other parts of the MIDDLE EAST; Europe, especially in SPAIN and ITALY; and the Andean areas of CHILE and ARGENTINA. They form where highlands border lowlands, and where the lowland basin area is smaller than the highland area. Often in mountainous terrain, two or more alluvial fans merge or cross each other. This forms a feature called a bajada or bahada, which extends into a flood plain. Like an alluvial fan, bajadas tend to be built of larger rocks and sediment near the mountains and channels that guide water to them, while finer silts mark their edges.

In the UNITED STATES, the Federal Emergency Management Agency (FEMA) can designate certain areas as natural hazards. After several catastrophic floods in

the late 1970s, FEMA began to evaluate the risks of flooding to alluvial fans. Some fans that were still subject to flooding presented attractive, gentle slopes for commercial or residential development. FEMA now decides whether such sites are hazardous based upon how susceptible they are to alluvial flooding and flood occurrence over a 100-year cycle, and how predictable the course of the floods will be.

## alluvium

THE SEDIMENT DEPOSITED by rivers is called alluvium. The name derives from the Latin word *alluvius*, meaning "washed up." Alluvium comprises clay, silt and sand (in some definitions gravel is included) and derives from the erosion of rocks and soils in the upper reaches of river basins. The mineral characteristics of the alluvium thus reflect its origins. It is carried downstream until the energy or sediment-carrying capacity of the river diminishes and the water can no longer carry the sediment in suspension.

During carriage, the sediment may be altered in physical character because of sorting and attrition. Sorting involves the separation of particles on the basis of size with finer and thus less dense particles like clay being carried farther downstream than larger and coarser particles such as sand and gravel. Attrition occurs as sediment particles collide during transport; overall, this causes a reduction in particle size and a general rounding in shape as angular material is smoothed.

The deposition of alluvium in river channels, on floodplains, in estuaries, deltas, and lakes takes place over time. The erosional, depositional, and attritional regimes of a river may also change over time depending

on climate and land-use characteristics in the river catchment.

Alluvium is widespread globally. It may provide fertile agricultural land because it is rich in nutrients, and it has provided the means for some of the world's great civilizations to develop and thrive. Examples include those of ancient EGYPT based on the NILE Valley, those of the Indus civilization in the valley of the same name, and those of ancient Mesopotamia in the Tigris and Euphrates Valleys. Today, some of the world's most productive agricultural land is on alluvium, as are many of the world's major urban areas, for example, LONDON, Bangkok, BUENOS AIRES, Cairo, MUMBAI (Bombay), and Shanghai. In many cases, there is conflict of interest in relation to land use as urban spread competes with agriculture and sediment extraction, such is the value and prized location of alluvial deposits.

Where alluvium comprises the fine particles of clay, it can be used for brick making and pottery, and where gravel predominates, it is sometimes excavated for use as road aggregate and building materials. If ore-bearing rocks occur in the upper catchment of a river, the alluvium resulting from their erosion may be sufficiently mineral rich to warrant extraction. The most important metallic minerals found in alluvium include tin, gold, and platinum. Precious stones such as diamonds may also be found if catchment rocks are a source of gem stones.

UNIVERSITY OF READING, UNITED KINGDOM

## Alps

THE ALPS ARE Europe's major mountain chain, occupying center stage between the cultural and geographic regions of western, eastern, southern, and northern Europe. Stretching in an arc about 600 mi (1,000 km) from west to east, the range covers parts of FRANCE, ITALY, SWITZERLAND, LIECHTENSTEIN, AUSTRIA, and SLOVENIA, with related features extending into GERMANY, CROATIA, and BOSNIA. Geologically, the mountains are at the core of even wider-reaching mountain systems, such as the Apennines and the Carpathians,

Once remote with practically impenetrable borders owing to the high mountains, Switzerland and parts of other countries within the Alps ranges are now more accessible with the construction of major mountain passes and tunnels.

and several lower chains on the outskirts (considered pre-Alps) such as the Jura in France, the Schwäbische Alb in Germany, or the Wienerwald in Austria—all were formed as a result of the collision of Italy and the Mediterranean floor with the landmass of Europe 150 million years ago. Several million people live within sight of the Alps, including residents of such major cities as Turin, Vienna, and Grenoble. The mountains—sometimes referred to as the “backbone” of Europe—have played a significant role in the history of Europe. Presently, the Alps are among the leading tourism locales in Europe, with about 100 million visitors per year, leading to challenges in growth such as overdevelopment and air pollution.

The origin of the name *Alps* is uncertain; it is most likely Celtic, perhaps for “white” or “high.” For many centuries the range was seen as a barrier between Mediterranean civilization and northern Europe, marked by heroic crossings like that of Hannibal with his elephants in 218 B.C.E. Mountain cultures in Switzerland, the Tirol, and southeastern France typi-

cally represented independence from authority and dogged defense of traditional freedoms, from William Tell to the perpetually neutral Swiss state of today. Gradually, the mountains were explored and valleys were settled. From the development of climbing as a sport in the 19th century and the engineering marvels of lengthy tunnels of the 20th century, the Alps ceased to be a threatening impasse, a land of avalanches and evil spirits, and became a recreation spot instead, a place of beauty. Notable sporting centers include Winter Olympic sites at Grenoble, Chamonix, Albertville, Garmisch, Innsbruck, and Cortina and ski complexes as Zermatt, Saint Moritz, and Bad Gastein.

There are numerous peaks over 12,000 ft (3,500 m), more than 1,200 glaciers, high carved-out circular basins called cirques, and sharp crags known as aiguilles. Long, narrow valleys separate high peaks, creating dramatic views, often accentuated by large, elongated lakes. These lakes are relics of the last Ice Age when glaciers dug deep trenches between the ranges: Lakes Maggiore and Como in Italy, Lakes

Geneva, Neuchâtel and Constance in Switzerland, and the series of interconnected lakes in central Switzerland are all generally long and very deep rather than wide. Other valleys were cut by swift mountain streams that form some of Europe's major rivers: the RHÔNE, the RHINE, the Po, and several major tributaries of the DANUBE, the Inn, the Mur, the Drava, and the Sava. These rivers carry water from the Alps as far away as the MEDITERRANEAN, North, and BLACK seas.

The Alps are traditionally divided into three sections, Western, Central, and Eastern, with numerous subdivisions within these. The border between France and Italy is delineated by the Maritime Alps, with peaks that emerge almost directly from the Mediterranean Sea, followed by the Cottian, Graian and Dauphiné (or Delphinic) Alps, and the Mont Blanc complex. Gran Paradiso, in the Graians, is the tallest peak entirely within Italy (13,648 ft or 4,061 m). Directly to the north is the double summit of Mont Blanc (15,771 ft or 4,806 m), the highest mountain in Europe outside of the Caucasus. The Mont Blanc massif is composed of several peaks and includes one of the longest vertical slopes in Europe (over 11,550 ft or 3,500 m), and the largest glacier in France, the Mer de Glace ("sea of ice") on the Col du Géant. A 7-mi (11-km) tunnel directly beneath the mountain connects ski resorts in France and Italy.

After traveling mostly northward from the Mediterranean, the Alpine chain turns a corner at the Mont Blanc group. Heading eastward, the mountains of the Central Alps form some of the highest and most famous portions of the Alps. Directly east of Mont Blanc, separating it from the Pennine Alps, is the Great Saint Bernard Pass, one of the highest passes in Europe and the site of a monastic hospice for travelers for nearly 2,000 years. The Pennines, forming the border of Switzerland and Italy, together with the parallel range of the Bernese Oberland to the north, form the quintessential Alps of postcard quality. Mountains such as the Matterhorn and the Jungfrau are immediately evocative of the Alps and Switzerland. The Pennine Alps contain 10 of the 12 highest peaks in the Alps. The Aletsch glacier is the largest in Europe, 16 mi (26 km) long, covering 50 square mi (130 square km). The Central Alps also include the mountains of southeastern Switzerland, the Lepontine, Bernina, Glarner, and Rhaetian Alps.

The Eastern Alps begin roughly at the watershed between the Rhine and Danube river basins. These chains tend to be less orderly in their organization, but continue to be more or less aligned in an east-west di-

rection. The Austrian Alps include the Bavarian range on the border with Germany (including Germany's highest peak, the Zugspitze, at 9,718 ft or 2,963 m, the Ötztal and Ortler ranges on the border with Italy, and the Höhe Tauern, with Austria's highest mountain, the Grossglockner (12,461 ft or 3,797 m). To the south, the Italian Dolomites have a slightly different character, with more rocks and less snow. Along Austria's southern frontier with Italy and Slovenia run the Carnic Alps, the easternmost part of the Alps proper. The Julian Alps are an offshoot to the south across Slovenia, with links to the lengthy mountain chain that runs down the length of the Adriatic coast, the Dinaric Alps.

SMITHSONIAN INSTITUTION

## Altai Mountains

THE ALTAI MOUNTAINS are a system of remote mountains in central Asia that cover an area of 326,256 square mi (845,000 square km) bounding RUSSIA, KAZAKHSTAN, MONGOLIA, and CHINA. This system is a natural marvel that has been largely untouched by large industries and has a very sparse population. Its name is derived from the Mongolian word *altan*, which means "golden." This region is home to many species of wildlife and plants and is made up of various landscapes. Most of the population in this region relies on farming and tourism.

The mountains stretch for 1,242 mi (2,000 km) from northwest to southeast, reaching a height of about 14,783 ft (4,506 m) at Belukha. Many rivers can be found in the Altai Mountains and most of them are fed by glaciers. Some of the largest rivers are Katun, Biya, and Chuya.

The glaciers cover an area of about 900 square mi (2,330 square km). Together with intensive river erosions, they have contributed significantly to the creation of the ruggedness of the region, where high waterfalls, steppes, and thousands of lakes can also be found. The deepest lake in the Altai Mountains, Telet-

skoe, is 1,066 ft (325 m) deep. The Altai Mountains are the source of the Ob and Irtysh Rivers, two of the major rivers in Asia. The region is rich in many natural resources like iron, gold, mercury, manganese, and marble. The United Nations Educational, Scientific and Cultural Organization (UNESCO) recognized the importance in preserving this eco-region and added five clusters of the Altai in the World Natural Heritage List.

The region is characterized by a continental climate with long, cold winters and short, cool summers. Snow starts covering the mountains during October and November, marking the beginning of winter. Temperatures hit the lowest in January, where they can range from 7 degrees F (-14 degrees C) in the foothills to -76 degrees F (-60 degrees C) in the STEPPES. In northern Siberia, one can find vast areas of permanently frozen soil. Summers begin somewhere between May and July and end in September. During this time temperatures often reach 75 degrees F (24 degrees C) during the day. Temperatures of 104 degrees F (40 degrees C) have also been recorded in the lower regions. At night, temperatures get cooler, usually ranging from 41 degrees F (5 degrees C) to 50 degrees F (10 degrees C). Elevations of 5,000 to 65,000 ft (1,500 to 19,000 m) experience high precipitation, usually ranging from 20 in (50 cm) to 40 in (1 m) a year. One aspect of the summer that many people appreciate is the lack of mosquitoes.

Four vegetation zones can be found in the Altai Mountains: the mountain subdesert, steppe, forest, and the Alpine areas. The most widely used plants and trees are cedar, badan, kuril tea, and cannabis. The subdesert has very little plant life; the few plants that exist are drought-resistant and salt-tolerant. Many sod grasses and shrubs can be found in the steppe. The forest is generally swampy and covers a large area in the low to medium mountain area. Here are found pines, firs, larches, and birch and aspen forests. The meadows in the Alpine region are used for pasture during the summer.

Wildlife is abundant in this region. There are 230 species of small birds, like woodpeckers, and 20 species of fish. Big mammals like bears, lynx, and musk deer are found mostly in the forest. In the Alpine region live reindeer, mountain goats, rams, and even rare animals like snow leopards. Some areas in the mountains are inaccessible to locals and visitors because they are used to study rare species of animals and plants.

The Altai Mountains are populated by mostly Altai and Russian settlers, many of whom moved there in the 19th century, mainly to escape religious persecu-

tion. The native population that was there before the 19th century continues to live in the old ways and is somewhat isolated from civilization. This area faces many challenges, especially with civilization knocking on its door. The big question is how to preserve the ecosystem and its natural beauty in spite of the increasing number of tourists and developments.

WIDENER UNIVERSITY

## Altiplano

THE ALTIPLANO IS A high plateau located in the central ANDES region of South America at an altitude of about 13,123 ft (4,000 m). It reaches into parts of PERU, BOLIVIA, CHILE, and ARGENTINA. On the west, it bounds the Cordillera Occidental and borders the Cordillera Oriental on the east. It is surrounded by volcanoes reaching altitudes of 19,685 ft (6,000 m), whose activities have caused landfalls that are responsible for the reshaping of this large plateau. The Altiplano has an area of 105,633 square mi (170,000 square km) that is volcanic in origin.

Lake TITICACA is the lowest point of the Altiplano, and occupies its northern basin. It is located at an altitude of 12,500 ft (3,810 m). It has an area of 5,632 square mi (14,587 square km) and reaches depths of 1,214 ft (370 m), making it the highest navigable body of water on earth. The large volume of water makes it possible for the lake to retain a stable 50 degrees F (10 degrees C) temperature. The lake plays an important part in affecting the surrounding climate. The southern basin of the Altiplano is occupied by shallow salt lakes and flats. Lake Titicaca drains into Lake Poopo through the Desaguadero River. Lake Poopo, which is a shallow saltwater lake whose depth rarely reaches more than 13 ft (4 m), is dependent on the flow of water from Lake Titicaca and seasonal rainfall. One of the largest salt flats in the Altiplano is the Uyuni Salt-

pan. It is all that remains of an ancient lake that covered an area of 5,592 square mi (14,483 square km). Today, this saltpan is filled with salt, which can be as deep as 16 ft (5 m).

The Altiplano's climate is characterized by a long dry season, lasting from April to November, and a short wet season. The wet season is from November to March, when 95 percent of the rainfall occurs. The amount of rain decreases from northeast to southwest. This is possible since a rain shadow effect is created that allows the northeast to receive more water. The Cordillera Oriental, for example, receives about 51 in (130 cm) of water annually, while the southern Altiplano receives only 6 in (15 cm). The atmosphere here is more transparent to radiation because of the greenhouse effect. This causes an increase in nighttime heat loss, which is noticeably greater than the rate at sea level. The ultraviolet radiation is 20 percent greater in the Altiplano than the radiation at sea level.

The highest temperatures during the summer are measured in late November, reaching 68 degrees F (20 degrees C) during daytime and falling to near 5 degrees F (-15 degrees C) at night. During the winter, June to August, mean temperatures reach as high as 55 degrees F (13 degrees C) and fall to 12 degrees F (-11 degrees C) at night. Strong winds are common in the Altiplano, reaching 62 mi per hour (97 km per hour). They are present nearly every day and are usually stronger in the afternoon.

The Altiplano ecosystem has a dry STEPPE climate, predominated by grasses. The lack of oxygen in the high altitudes of the Altiplano allows only a few plants and animals to survive. Some of the animals living in the region are condors, flamingos, different species of cameloids (e.g., American camels), llamas, alpacas, and many bird species. The Altiplano is also home to the quinoa tree, which grows at an elevation of over 11,500 ft (3,500 m).

The Altiplano has been home to the Inca peoples. Today, some of its areas are populated by Aymara natives. Since the Inca's time, the plateau has seen much mining: Gold and silver are two of the metals sought by miners and mining companies. Other natural resources include tin, natural gas, petroleum, zinc, tungsten, antimony, silver, iron, and lead. Mining has been the source of pollution to the air, water, and soil in the Altiplano.

ARTHUR HOLST, PH.D.  
WIDENER UNIVERSITY

## Amazon Rainforest

THE AMAZON RAINFOREST is the largest rainforest in the world. It extends for 3,000 mi (4,828 km) from the ANDES mountains to the ATLANTIC OCEAN. The rainforest covers parts of BRAZIL, PERU, ECUADOR, COLOMBIA, BOLIVIA, and VENEZUELA, encompassing over a billion acres and covering one-third of South America. The 6,500 mi (10,461 km) of the great AMAZON RIVER, second only to the NILE RIVER in length, flows throughout the rainforest. Eleven hundred tributaries, some of which are over 1,000 mi (1,609 km) long, feed into the Amazon River.

Since the rainforest is close to the equator, its CLIMATE is hot and humid at all times. From 40 to 80 in (100 cm to 200 cm) of rain falls annually in the eastern section of the rainforest, while the western region experiences around 160 in (400 cm) of rain each year. THUNDERSTORMS occur more than 200 days of the year. In sections of the rainforest that are closest to the equator, rain falls almost constantly. Trees within the rainforest are always green, but many shed their leaves in response to biological and climatological changes.

The Amazon Rainforest is considered a resource for the entire world, in part because of the plant life that protects the world's environment from the greenhouse effect. When the rainforest performs its natural function, at least 50 percent of the rain returns to the atmosphere on the leaves of trees through the process of evapotranspiration. This process uses the water loss from the trees in the rainforest to form clouds that make rain in other, more protected parts of the rainforest area.

The rainforest is made up of four layers: the emergent layer, the canopy, the understory, and the forest floor. The emergent layer is located at the top of the trees of the rainforest. This layer is subject to intensive amounts of sunlight, high temperatures, low humidity, and strong winds. The canopy, sometimes called the upper canopy, is made up of the tallest trees in the forest. These trees, which may grow to 200 ft (61 m), pro-

tect the land below from harsh sunlight. The middle layer of the rainforest, known as the understory or lower canopy, may be as high as 20 ft (6 m). It is made up of various small trees, vines, and shrubs. The forest floor or the jungle is composed of ground cover such as herbs, mosses, and fungi. The wildlife in this section of the rainforest eats roots, seeds, leaves, fruit, and smaller animals.

Around two-thirds of all animals and plants in the rainforest inhabit the canopy. For instance, in a section of a canopy in the Peruvian rainforest, scientists identified over 50 species of ants, 1,000 species of beetles, some 1,799 arthropod species, and approximately 100,000 species of fauna. Samples taken from canopies in PANAMA, Brazil, Peru, and Bolivia revealed over 1,500 species of beetles in each canopy. Because the canopy area is not easily accessed and because many insects find shelter underneath the leaves, it is thought that thousands of species may yet be discovered. Some species of wildlife spend their entire lives in the trees of the rainforest.

Poverty, population growth, greed, and shortsightedness have historically been the major threats to the Amazon Rainforest. Construction, which often operates on the principle of “slash and burn,” has created a new threat since the middle of the 20th century. For instance, in February 2001, officials in Ecuador contracted with an international consortium to construct the 300-mi (483-km) Oleoducto de Crudos Pesados (Heavy Crude Pipeline) intended to transport crude oil from the rainforest to the Pacific Coast, affecting forests and wildlife and displacing native inhabitants.

### RAINFOREST SOILS

Three major soil types have been identified within the Amazon Rainforest. One layer, known as ultisols, is made up of kaolinite clay and minerals that are transported from flooded upper soil levels. This acidic soil, containing aluminum compounds, is not conducive to plant life.

A second layer, called oxisols, which is made up solely of kaolinite clay, is thick and sticky and virtually unusable to plants. Spodosol soils, which are found in higher lands that are not subject to flooding, tend to be sandy and acidic and are incapable of retaining nutrients. Soils in the rainforest are generally unable to absorb water, further contributing to the difficulties that local farmers face. On the other hand, soils within wetter parts of the rainforest provide an excellent growing area for exotic tropical plants, many of which serve as food for animals in the rainforest.

*Many animals live in the busy canopy or treetop layer of the Amazon Rainforest shown above.*

### FAUNA AND FLORA

Around 80 percent of all food eaten by the people of the world today originated in the tropical rainforests, including over 3,000 species of fruit. Edible produce from the Amazon Rainforest include: Brazil nut, cashew, banana, fig, coffee, cocoa, vanilla, passion flower, breadfruit, yucca, avocado, coconut, orange, lemon, grapefruit, guava, pineapple, mango, tomato, corn, tomato, potato, rice, winter squash, yam, black pepper, cayenne pepper, chocolate, soybean, cinnamon, clove, ginger, sugarcane, tumeric, and coffee. Orchid, philodendron, bamboo, mahogany, and rubber fungus are also found in the rainforest.

More animals and plants are found within the Amazon Rainforest than in the rest of the world combined. At least 500 species of mammals, 175 varieties of lizards, 300 species of other reptiles, and innumerable species of tree climbers are among the many animals identified so far. Scientists and environmentalists believe that there are thousands of species of wildlife in the rainforest that have yet to be identified. Some of the animals found in the rainforest include anaconda, ant, anteater, beetle, boa constrictor, pit viper, butterfly, katydid, piranha, capybara, caiman, coatimundi,

*The Amazon Rainforest is perhaps the largest resource in the world, referred to as the “lungs of the planet.”*

kinkajou, puma, tarantula, tree frog, moth, tapir, cockroach, iguana, jaguar, cougar, deer, lemur, orangutan, marmoset, pink dolphin, wild dog, wolf, raccoon, otter, ocelot, three-toed sloth, mosquito, bot fly, bat, and termite.

One-third of the world's birds reside in the Amazon rainforest, including the macaw, parrot, toucan, harpy eagle, crow, ant bird, and umbrella bird. Approximately one-fifth of all freshwater fish are found in the Amazon Basin. Unfortunately, a number of unscrupulous individuals have engaged in illegal wildlife trading, decreasing the number of animals found within the rainforest and further threatening the natural balance of life there.

## PEOPLE

Gonzalo and Francisco de Orellana, two Spanish explorers, discovered the Amazon River region in 1541 while looking for valuable minerals and spices. They encountered native people, including a band of women warriors who became known as Amazons. Many of the native people died from diseases brought by explorers to the New World or from being enslaved. Whole tribes were wiped out. In the 16th century, over 10 mil-

lion natives resided in the Amazon Rainforest. That number had decreased to less than 200,000 by the beginning of the 21st century.

In Brazil, for example, only 10 percent of the original tribes remain. Some of the poorer members of the tribes that inhabit the Amazon Rainforest today survive on subsistence farming, further destroying valuable resources. Natives within the rainforest eat cassava, yucca, fruits, nuts, fish, insects, and animals such as rabbits, deer, and wild pigs that they shoot with rifles or blowguns. Some tribes, such as the Kayapó, have become more Westernized, enjoying bank and money market accounts, airplanes, tractors, bulldozers, and other luxuries of modern life.

## RAINFOREST DESTRUCTION

James Alcock, a professor at Pennsylvania State University, has estimated that at the current rate of destruction, the point of no return in the Amazon Rainforest could be reached as early as 2016. Unchecked destruction could entirely wipe out the rainforest by the middle of the 21st century. Poverty, population growth, greed, and shortsightedness have historically been the major threats to the Amazon forests. Construction, which often operates on the principle of “slash and burn,” has posed a serious threat since the middle of the 20th century. Much of the Amazon Rainforest was destroyed by João Baptista Figueiredo, the president of Brazil who built the Trans-Amazonian Highway, destroying vast tracts of the forest in western Brazil. This highway provided a means for loggers, ranchers, builders, prospectors, and a variety of other people and businesses from around the world to flock to the rainforests, speeding up its destruction. Fire has also become a major threat in recent years as the rainforest has become drier. The fragile lands of the rainforest are also being used for cattle grazing and subsistence farming. The worst period of destruction in the rainforest came between 1978 and 1990 before the destruction of the rainforest became widely known.

Francisco Alves “Chico” Mendes Filho, a Brazilian rubber tapper, union organizer, and ecologist, became the voice of those who were determined to educate the world about the Amazon Rainforest. Mendes was instrumental in the foundation of the National Council of the Seringueiros and helped to plan the extraction reserves, which created government-owned conservation areas designed to give rainforest natives control over the production and protection of the Amazon Rainforest. Mendes was murdered on December 22,

1988, in the doorway of his home. Through the efforts of the Chico Mendes Committee, Darly and Darcy Alves de Silva were charged with his murder. Mendes's death galvanized the conservationists and enhanced their efforts to protect the rainforest.

Some scientists believe that as much as 30 acres of rainforest are being destroyed every minute in the rainforests of the world. As acre after acre of rainforest is being destroyed, nature's natural shield is disappearing, since there are fewer trees to use the carbon dioxide as food through a process called photosynthesis. As a result, levels of carbon dioxide in the atmosphere are increasing every year.

Intrusions into the rainforests have also destroyed valuable resources such as medicinal plants, quinine, muscle relaxers, steroids, and various cancer-fighting drugs. Seventy percent of the 3,000 drugs with cancer-fighting properties that have been identified by the U.S. Cancer Institute are found in the Amazon Rainforest. American drug companies are so convinced of the potential for finding further disease-fighting drugs in the rainforest that some 100 companies have funded projects to study the plants used by native inhabitants of the rainforest for thousands of years.

One third of the Amazon Rainforest is located in Brazil, where authorities believe that as much as 80 percent of all logging done in the rainforest is done illegally. In 2003, authorities launched a satellite system designed to prevent illegal logging in the rainforest. Brazil has also begun to levy fines against multinational corporations that engage in illegal logging.

Peru has been losing approximately 716,000 acres (289,755 hectares) of rainforest a year. In March 1992, the nonprofit Amazon Center for Environmental Education and Research Foundation (ACEER) opened the Amazon Biosphere Preserve in Peru to increase knowledge of the Peruvian rainforest and to provide protection for this fragile resource. One way that ACEER has done this is through the erection of a canopy walkway project that allows greater access for scientists to study the living matter that resides in the rainforest. The walkway also provides tourists with a firsthand look at the mysteries of the Peruvian rainforest. ACEER's facilities include also bird and butterfly preserves.

Ecuador has been much more remiss than either Brazil or Peru in protecting its section of the Amazon Rainforest. Ecuadorian authorities have permitted logging, road construction, and oil exploration to destroy approximately 466,800 acres (188,907 hectares) of rainforest a year. In February 2001, officials in Ecuador contracted with an international consortium

to construct the Oleoducto de Crudos Pesados (Heavy Crude Pipeline) intended to transport crude oil from the rainforest to the Pacific Coast, destroying forests and wildlife and displacing native inhabitants. As a result, only 1 percent of Ecuador's rainforest has survived.

The rainforest in Colombia is host to over 1,815 species of birds, 590 species of amphibians, and 3,200 species of fish. Like Ecuador, Colombia has done little to check the problems caused by illegal logging, mining, pollution, agriculture, and illegal animal piracy. Similarly, Bolivia has done little to stop multinational logging companies and cocoa and soybean farmers from destroying much of its section of the Amazon Rainforest.

Venezuela has had the additional problem of dealing with oil exploration within its region of the rainforest. Big oil companies destroyed much of Venezuela's forests before 1974, when authorities nationalized the oil industry. Belatedly, the Venezuelan government created a number of national parks and passed protective legislation and recognized the rights of native inhabitants of the rainforest.

## Amazon River

SOME AUTHORITIES believe that the river in BRAZIL and neighboring countries was named after the Amazons, women warriors of Greek mythology, who were thought to reside in the region; other scholars insist that the name is derived from the local native word

*The Amazon River basin covers a good portion of Brazil, Bolivia, Peru, and Colombia in South America.*

*amassona*, meaning “boat destroyer.” Despite centuries of effort to overcome the dominance of nature, people have made little impact on the Amazon and most of its vast drainage basin. No bridge spans the river. Except near its mouth, the Amazon watershed constitutes one of the most thinly populated regions in the world. Much of the territory drained by the river system has never been thoroughly explored. One may fly for hours over the tropical forests that cover much of the river’s FLOODPLAIN and see no sign of human settlement. In many valleys, native tribes remain hostile to strangers, continuing to live much as they did before the arrival of the Europeans.

### BASIN GEOGRAPHY

The Amazon Basin is a vast structural depression covering approximately 2,722,000 square mi (7,049,800 square km), an area nearly as large as the continental portion of the UNITED STATES. It is twice as large as the world’s next largest drainage BASIN (the CONGO RIVER), and supports the world’s largest rainforest. Geologi-

cally, two large stable masses of Precambrian rock, the Guyana Shield or Highlands to the north and the Central Brazilian Shield or Plateau to the south, bound the Amazon River and basin. Some 15 million years ago, before the ANDES MOUNTAINS were formed, the Amazon River flowed westward into the PACIFIC OCEAN. With the uplift of the Andes Mountains, however, the course of the river was eventually blocked to the west. As the river system backed up, the environment of the Amazon basin changed and numerous freshwater lakes began to form an inland sea. Ultimately, the gradient and volume of water was sufficient to push the flow to the east toward the ATLANTIC OCEAN where it empties today.

Most sources list the Amazon as 4,080 mi long (6,580 km), making it second to the NILE in length. However, there is some debate about the length of the Amazon versus Nile depending on the actual starting point of the source. According to recent discoveries, the Amazon is 4,195 miles (6,712 km) long if the course follows the Apurimac branch (rather than the Urubamba branch) of the Ucayali to a point 17,200 ft (5,242 m) above sea level, making it 50 mi (80 km) longer than the Nile. The Ucayali and Marañon rivers, both of which rise in the permanent snows and glaciers of the high Andes Mountains, flow along roughly parallel courses to the north before joining near Iquitos, Peru. Beyond Iquitos the river turns abruptly eastward, flowing along a very gentle gradient (approximately 1.25 in or 3.2 cm per mile) more or less paralleling the equator as it meanders over lowland plains. At Manaus, approximately 1,000 mi (1,610 km) upstream from the coast, the elevation is only 100 ft (30 m) higher than Belem, which is an ocean port.

The northern half of the South American continent is shaped like a shallow dish. More than 1,000 tributaries, seven of which are more than 1,000 mi (1,613 km) long, flow through nine South American countries (Brazil, BOLIVIA, PERU, ECUADOR, COLOMBIA, VENEZUELA, GUYANA, SURINAME, and FRENCH GUIANA) that contribute waters to this dish. Beyond the riverbanks there are broad, swampy floodplains covered with lush, periodically flooded forests.

Throughout most of the Brazilian part of the river, the channel exceeds 150 feet (50 m) in depth, although some parts near the mouth have been recorded to be as much as 300 feet (91 m) deep. Discharge at the mouth of the Amazon is approximately 7,733,000 ft cubed per second (219,000 meters cubed per second), nearly five times the volume of the Congo and roughly equal to the volume of all the other major rivers of the world

combined. At some points, the Amazon is 1 mi (1.6 km) wide, while at other points during the flooding season it can be 35 mi (56 km) wide or more. At Belem, where the waters flow into the Atlantic Ocean, it can be 200 to 300 mi (322 to 483 km) across, depending on the season and including the river's influence along the coast.

At Iquitos in Peru, the furthest point up river for major navigation by ship, the river also changes its name. From Iquitos to the junction of the Rio Negro near Manaus the river is known locally as the Solimoes, while from Manaus to the sea it is referred to as the Amazon.

## CLIMATE

Over most of this vast region the CLIMATE is very warm and humid. Rain falls about 200 days each year, and rainfall totals often exceed 80 in (204 cm) per year. One result of so much rain is that the Amazon is subject to seasonal floods. Tributaries flowing from the south tend to flood from February to April, while those coming from the north reach flood peaks between June and July. As these waters make their way to the sea, the waters of the Amazon vary in color depending on the soils and rocks they pass over. Some of the tributaries are home to "white" waters, although their color is more often a murky yellow or tan than white. The white rivers originate from runoff in the Andes, and their turbidity results from the heavy loads of mud and silt they carry.

Waters in so-called black rivers, on the other hand, come from areas where the water flows over ancient rocks where there is little sediment remaining to be washed away. The black rivers are dark because only dissolved organic matter stains their clarity. Clearly the most dramatic union of black waters with white occurs at Manaus, where the black waters of the Rio Negro and the ochre-tinted Rio Solimões meet. Locally known as the Encontro das Aguas (Wedding of the Waters), the waters run side by side for miles before they finally mix.

There is some evidence suggesting that the lower Amazon may once have been an ocean gulf, the upper waters of which washed the cliffs near Obidos some 600 miles (966 km) from the coast. The effects of the ocean are still felt at Obidos. Because of the gentle slope of the land, tides are able to penetrate this far upstream. Here the tidal phenomenon called the bore, or Pororoca, occurs. Often up to 12 ft (3.7 m) high, it begins with a roar, constantly increasing as it advances at a rate of from 10 to 15 mi (16 km to 24 km) an hour

Beyond the point where the Zingu River joins the Amazon from the south, the main channel splits into a maze of smaller channels with numerous large islands. Marajo, the biggest island in the delta, is about the size of Vermont and New Hampshire combined. Finally, beyond its several mouths, the Amazon merges with the sea just above the equator where ocean currents bend it northwestward along the coast ultimately becoming part of the South Equatorial Current.

## THE RAINFOREST

The Amazon rainforest, also known as Amazonia, is the largest tropical rainforest in the world, covering more than half of Brazil. It is also one of the world's greatest natural resources, containing the largest single reserve of biological organisms in the world. No one really knows exactly how many different species inhabit the area, but scientists estimate there are between 800,000 and 5 million, amounting to 15 to 30 percent of all the species in the world. Because its vegetation continuously recycles carbon dioxide into oxygen, it is often referred to as the "Lungs of our Planet."

The Amazon Rainforest consists of four layers or communities. Each layer has unique ecosystems, plants, and animals adapted to that system. The emergent layer is the tallest layer, where trees can be as tall as 200 ft (61 m) and rise well above the canopy. Here they are exposed to fluctuation of temperature, wind, and rainfall. The leaves are small and covered with a thick waxy surface to hold water. They take advantage of the wind by developing winged seeds that are blown to other parts of the forest. Trunks can be up to 16 ft (4.9 m) around and braced by massive buttress roots. Some of the animals find everything they need to survive in the emergent layer and never leave it.

The main layer of the rainforest is the canopy. Most canopy trees have smooth, oval leaves that come to a point, known as a drip tip. This allows water to flow off the leaf quickly and prevents the growth of fungi, mosses, and lichens. The canopy's leaves are very dense and filter out about 80 percent of the sunlight. Many flowers and fruits grow in this layer. Epiphytes cover every available surface and bromeliads provide drinking water for the many canopy creatures and breeding pools for tree frogs.

Some of the animals found in the canopy are the harpy eagle, which preys on monkeys, kinkajous, sloths, reptiles, and other birds. Sloths spend most of their lives in the treetops. Their diet of low-nutrition leaves forces them to conserve energy, causing the sloth to spend 80 percent of its life resting. A large portion of

a howler monkey's diet consists of leaves that are hard to digest. Their metabolism is so low that they need to warm themselves up in the sunlight after a chilly night. Leaf-cutter ants are responsible for harvesting a sixth of the area's leaves, bringing leaf fragments to their underground nests. They play a critical role in the rainforest's ecosystem by pruning the vegetation, which stimulates new growth, and breaking down the leaves to renew the soil.

The understory receives only a small amount of the available sunlight. Plants must find unique ways to adapt to this shadowy existence. Their leaves tend to grow large and are darker green than the leaves found in the main and emergent layers. Vegetation in this zone also tends to be relatively short, growing little more than 12 feet in height. Because there is very little air movement in this zone, the plants must rely on insects and animals to pollinate their flowers. Accordingly, the flowers and fruits of plants in this zone are usually quite large and grow low on the trunks. The lack of wind and abundant sources of flowers and fruits also makes this the layer with the largest concentration of insects.

The forest floor is the lowest layer. It has relatively few plants since only 2 percent of the available sunlight filters through to this level. The floor is littered with decomposing vegetation and organisms that break it down into usable nutrients. Many nutrients are locked into this biomass. Tree roots stay close to the surface to access these nutrients rather than penetrating very far into the soil. Large animals forage for roots and tubers, while insects like millipedes, scorpions, and earthworms use the litter as a source of food.

## PIRANHAS

Naturalists suggest there may be as many as 3,000 different kinds of fish in the Amazon's rivers and lakes. Among these are some of the biggest fish outside the ocean. Among the fish found in the area are the pirarucu, said to be the largest freshwater fish in the world, with some specimens measuring over 6.5 ft (2 m) in length and weighing 275 pounds (125 kg); the tambaqui, which have teeth that can crack seeds as hard as those of the rubber tree and the jauari palm; and the piranha. The ferocity of the meat-eating piranha has been exaggerated. Although it is true that some species have killed large animals and even people, their behavior depends on the state of their habitat and violence toward humans is a rare circumstance. In main river channels and in larger lakes with plenty of food available, they generally pose no threat to swim-

mers. They appear to become aggressive only when they do not have enough nourishment.

Over 500 mammals, 175 lizards and 300 reptiles species, and one-third of the world's birds live in Amazonia. It has been estimated that about 30 million insect types can be found here. Competition for survival is fierce, with the most intense competition taking place between animals and plants.

Despite the abundant riches, the giant trees that grow within the rainforest structure also grow in some of the world's poorest (least nutritious) soils, with the top two inches containing 99 percent of the nutrients. Nine-tenths of the forest's energy is stored in the leaves and tissues of the trees themselves. As soon as a tree falls, decomposers begin to turn it into a food source, as the vegetation to renew the cycle quickly absorbs the nutrients that are released. Because the rainforest ecosystems are the most efficient in all of nature, the destruction of one part of the system can spell the destruction of the whole system.

The climate throughout Amazonia is about the same throughout the year, and the difference between day and night time temperatures is usually greater than that between seasons. Temperatures are warm and humid, averaging around 79 degrees F (26 degrees C).

## EXPLORATION AND ECONOMY

There is archaeological evidence of clustered, densely populated pre-Colombian settlements in parts of the Amazon basin, but at the time of the early European explorations, these settlements had already been wiped out, probably by smallpox and other diseases. The Amazon was probably first seen by Europeans in 1500 when the Spanish commander Vicente Yáñez Pinzón explored the lower part. Real exploration of the river came with the voyage of the Spanish explorer Francisco de Orellana in 1540–41. Not long afterward (1559) the Spanish conquistador Pedro de Ursúa led an expedition down from the Marañon River. In 1637–38 the Portuguese explorer Pedro Teixeira led a voyage upstream that ultimately opened the Amazon. The valley was largely left to its sparse remaining indigenous inhabitants until the mid-19th century, when a few settlements were started and steamship service was established.

In the late 19th and early 20th centuries, the wild-rubber boom on the upper Amazon attracted settlers from Brazil's northeastern states, while Japanese immigrants began developing jute and pepper plantations in the 1930s. Until recently the area has remained largely unpopulated, yielding small quantities of forest prod-

ucts (rubber, timber, vegetable oils, Brazil nuts, and medicinal plants) and cacao. Extensive road networks are now opening the land to colonization, although agricultural success has been limited by adverse climate, poor soils, and the lack of nearby markets.

In the 1960s, the Amazon region began experiencing increased economic development brought on by tax incentives to settle in the west from the Brazilian government and construction of the Trans-Amazon Highway, the Belém-Brasília Highway, and two rail lines. Near Manaus and Amapá, factories are making use of the areas oil and manganese resources.

The Brazilian government implemented a “poles of development” policy in 1974 to plan for population increases in the west. Since 1985, the Carajás project has seen the development of major iron ore deposits, the construction of a new railroad, and the initiation of forest clearance, land colonization, cattle ranching, large-scale farming, and urban development on an unprecedented scale. This policy has had mixed results, however, with significant environmental damage and disruption of native inhabitants’ lives. Over the past 30 years, government-sponsored road-building projects, colonization schemes, and industrial developments have transformed large areas of Amazonia from pristine forest to polluted factory sites and sprawling settlements.

In spite of the numerous development programs, the economy through most of the basin continues to be dominated by primitive agriculture, hunting and fishing, and the gathering of various forest products. Commercial farming, tourism, and industry play only a minor role in the region, but manufacturing, mining, and lumbering, the principal economic activities, are increasingly important.

## MAJOR CITIES

Although there are a few sizable cities along the river’s banks and scattered settlements inland, Amazonia is largely uninhabited. Here and there, plantations have been cleared in the jungles, and natives ply the streams in search of latex and Brazil nuts. But mostly the great green luxuriant rainforest is still pristine wilderness, one of the few large areas left on Earth where nature’s creation remains more or less unspoiled and intact.

For 350 years after the European discovery of the Amazon by Pinzon, the Portuguese portion of the basin remained an almost undisturbed wilderness. It is doubtful if its indigenous inhabitants ever exceeded one to every 5 square mi (13 square km) of territory. A few early settlements on the banks of the main river

and some of its tributaries had been founded by the Portuguese, either for trade with the Indians or for evangelizing purposes. The total population of the Brazilian portion of the Amazon basin in 1850 was perhaps 300,000, of whom about two-thirds were white and slaves, the latter numbering about 25,000.

Manaus, the largest early settlement along the Amazon, is once again one of Brazil’s major cities. Although located 1,200 mi (1,931 km) from the Atlantic, it is a port city with a population of 750,000. Manaus is downriver from the famed “Wedding of the Waters,” or Encontro das Aguas, where the dark Rio Negro and the ochre-tinted Rio Solimões meet and run side by side for some miles before they finally mix. The city was built during the rubber boom, when the Amazon had the only rubber trade in the world. The city enjoyed unbelievable wealth through the turn of the 20th century, with lavish living, splendid buildings, and huge plantations springing up out of the jungle. The rubber trade created a thriving city that attracted entrepreneurs from the United States and Europe. Ultimately, traders found a way to take some of the plants to India and started growing them. With new sources of rubber, the market became oversaturated and eventually collapsed, leaving the cities tied to the rubber trade with the same fate. Today, the city is busy because of government programs encouraging development of Brazil’s west, a duty free zone, and the creation of an active tourist industry.

Belém, the largest of the three major river cities, is located on the Para River, a tributary of the Amazon near the mouth of the Amazon. Belém was founded in 1616 as a fort. During the rubber boom the city was a hot spot of European culture. A port city, it is the capital of the state of Para. The market place in Belém, Vero-O-Peso, is the largest in Brazil.

Iquitos holds the distinction of being the world’s most inland seaport and is accessible only by land or by water. It is the fourth largest city in Peru and the third largest port city on the Amazon. Founded in the 1750s as a Jesuit mission, Iquitos boomed during the rubber days. But the end of the rubber boom in 1920 left the town almost deserted. Today Iquitos is an export center for live animals and aquarium fish, an oil center, and the staging spot for tourism. It also has the largest floating market on the Amazon.

## ISSUES AND CONCERNS

Today, more than 20 percent of the Amazon Rainforest has been destroyed. The land is being cleared for cattle ranches, mining operations, logging, and subsistence

agriculture. Some forests are being burned to make charcoal to power industrial plants. Because rainforest soils are heavily leached, they lack the ability to sustain agriculture for more than a few seasons. Once cut, for whatever reason, a rainforest is likely gone forever. With its passing go untold numbers of species yet discovered as well as habitat and diversity for those that remain. The loss of rainforest also impacts indigenous people by eliminating the hunting and gathering habitat that has sustained them for thousands of years. Today there are fewer than 200,000 indigenous peoples left in Amazonia, and more than 90 tribes have been destroyed since the 1900s

Indigenous peoples have also used different plants as cures and potions for their health and survival. Many of our current pharmaceuticals are based on medicinal chemistry derived from the plant kingdom. Today more than 100 prescription drugs come from plant-derived sources. And although only 25 percent of all drugs are derived from rainforest ingredients, scientists have tested only 1 percent of the potential number of tropical plants that could be available.

In the 1980s, under pressure from international conservation groups, Brazil started to ensure that development efforts in the Amazon did not irrevocably compromise the forest resources. Although recent discoveries of oil and gas have placed increasing pressures on the natural wealth of Amazonia, the Brazilian government has been active in promoting sustainable exploitation policies to manage the Amazon's huge resource reserves. Environmental monitoring and licensing systems have been set up along with national parks to conserve the flora and fauna. Additionally, the rights of Indians and their way of life have been recognized and protected within the reserve system.

## American Samoa

AMERICAN SAMOA, a territory of the UNITED STATES in the PACIFIC OCEAN, consists of the eastern half of the Samoan archipelago and comprises five volcanic islands: the main island of Tutuila and its smaller partner, Anu'u, plus the islands of Ofu, Olosega, and Ta'u (the Manu'a Islands) to the east.

The territory, with its capital at Pago Pago, is 77.6 square mi (199 square km) and has a highest point at Lata of 3,188 ft (966 m). It has a population of 70,260. The territory also includes the more distant coral atolls, Rose and Sand, and tiny Swains Island, far to the north. The islands extend roughly 186 mi (300 km) from west to east and are located about two-thirds of the way from HAWAII to NEW ZEALAND.

The main town and administrative center, Pago Pago, has one of the best natural deepwater harbors in the South Pacific Ocean, protected from rough seas and high winds. Strategically located at the crossroads of the South Pacific, the harbor at Pago Pago attracted the attention of the U.S. Navy as early as the 1870s and remained a primary coaling point for U.S. ships crossing the Pacific until the end of World War I, when oil replaced coal in most larger vessels. Since then, American Samoa has remained a relative backwater and has thus retained much of its traditional way of life, unlike many of its neighbors.

American Samoa's nearest neighbors are the sovereign states of [Western] SAMOA and TONGA to the west and southwest and the New Zealand dependencies of Tokelau, Cook Islands and Niue to the north, east, and south. The islands lie just to the east of the INTERNATIONAL DATE LINE and at the intersection of the three cultural divisions of POLYNESIA, MICRONESIA, and MELANESIA, though the Samoans themselves fall within

the Polynesian sphere. The islands are volcanic in origin, with rugged peaks and limited coastal plains.

The climate is tropical marine, with ample rainfall, stimulating dense forests on most the islands and allowing cultivation of bananas, coconuts, taro, breadfruit, yams, copra, pineapples, and papayas. Industries are limited to several large tuna canneries, plus local handicrafts and garments. Tourism is not heavy, since there is limited airline service. The canneries were opened in the 1950s and 1960s and constituted 90 percent of all exports in 1995. But few locals want to work there, so half the labor force are aliens, mostly from Western Samoa and Tonga. Young American Samoans are increasingly leaving for the mainland United States for higher education and employment opportunities. The population thus varies widely (for example, in 1984 it was given as only 36,000). About 90 percent live on Tutuila, mostly near Pago Pago.

The islands were settled long before European contact in the 18th century. Native chiefs looked to the United States in the late 19th century for protection against the squabbles of European colonial powers. The first treaty with a local chief allowing U.S. boats to anchor in Pago Pago Harbor was signed in 1872, and negotiations between Great Britain, Germany, and the United States led to a partition in 1899 (at 171 degrees west longitude), though the ranking Samoan chiefs did not formally cede their territories until 1904 (after the United States had already set up its administration).

The larger islands in the group, Upolu and Savai'i, went to Germany and from 1962 formed the independent nation of Samoa. The population of the eastern islands in 1900 was less than 6,000. After World War I, the Samoans were mostly left to themselves, and their traditional system of government and family-based communal landownership was preserved. Subsistence economy was successful and local traditions were strong, so many Western influences were either rejected or, like Christianity, molded to fit the Samoan way.

Since 1951 the islands have fallen under the jurisdiction of the U.S. Department of the Interior, and a new constitution was adopted in 1966, but, unlike America's other territories in the Pacific, there is little desire to change the status quo, either toward independence or toward closer affiliation with the United States. The islands rely on heavy subsidies and welfare programs but are also wary of losing their traditional way of life by submitting entirely to U.S. law (for example, the continuation of government leadership by semi-hereditary chiefs, the matai, and the system of

communal landholding, under which about 92 percent of the land continues to be held by traditional kin groups). American Samoa thus remains an unorganized, unincorporated territory of the United States. Samoans are mostly self-governing, and strict restrictions of immigration are intended to preserve their autonomy and traditional culture.

## Amu Darya

THE AMU DARYA has served as a bridge between cultures for several millennia. A river that flows straight across one of the harshest deserts in the world, it has served as a natural highway for migrants and invaders from Central Asia to South Asia and the MIDDLE EAST, as well as a boundary for the empires established by these same invaders. The Amu Darya starts high in the HINDU KUSH mountains at the boundaries of AFGHANISTAN, KASHMIR, CHINA, and TAJIKISTAN, at an elevation of 16,170 ft (4,900 m). From there, it descends rapidly to the great central Asian lowlands, which are mostly covered by the Kara Kum and Kyzyl Kum deserts. Much of the river's water is lost to evaporation and irrigation, so water levels are actually lowest when it finally reaches its mouth in a large delta on the ARAL SEA, 1,500 mi (2,419 km) later.

The river was known as the Oxus (or the River Styx, River of Hades) to the ancient Greeks and formed the northern extremity of the lands conquered by Alexander the Great in the 4th century B.C.E. The lands that now form UZBEKISTAN and KAZAKHSTAN were thus known for much of their history as Trans-Oxiana. The river's current name comes from the ancient city of Amulya (near Chardzhou), plus *darya* (Turkic for "river"). Irrigation has long been vital to cities in the region, cities whose importance was heightened as stops on the SILK ROAD from Persia to China. Important sultanates grew up around the cities of Khiva, near the

delta, and Bukhara further upstream, near the confluence of the deserts and the foothills of the great mountains to the east. Fertile desert soils, watered by the Amu Darya and bathed in unending sunshine, were famous for their production of extra sweet fruits, notably apricots, dates, and melons, and aromatic plants such as lavender and sage. Imperial Russian and later Soviet administrations increased the development of irrigation of the Amu Darya valley, making Uzbekistan into a leading producer of cotton, but have also caused the ARAL SEA to shrink to in size. At some times during low water, the Amu Darya does not even reach the Aral at all.

The Amu Darya basin drains 208,558 square mi (534,764 square km), including most of Tajikistan, northern Afghanistan, and a small area of south KYRGYZSTAN. Seventy-two percent of the basin is arid, while 22 percent is cropland through irrigation. Nearly from its source in the Wakhan panhandle of northeastern Afghanistan, the river serves as the border between that country and Tajikistan, and is fed by several swift-moving mountain tributaries from both countries.

The river is called the Vakhsh Darya until it is joined by the largest of these tributaries, the Vakhsh, from Tajikistan, then assumes the name Amu Darya. At its emergence from the foothills of these great mountains, the river valley becomes the border between Uzbekistan and Turkmenistan, though much of the river itself lies within the latter until the city of Chardzhou, and within the former from Khiva to the delta. In this segment, the river is slow and wide and receives no tributaries at all and very little rain, thus losing approximately 25 percent of its volume before it reaches the Aral Sea.

Chardzhou, the largest city in northeastern Turkmenistan, marks the boundary between semidesert and desert; from this point on, the sands of the Kara Kum approach the river directly and add considerably to the already heavy load of silt, sand, and mud being carried by the river from the mountains. The Amu Darya is considered the most heavily silted river in the world, with its high volume of suspended material giving it its characteristic murky yellow coloring.

The eastern parts of the river in Turkestan have natural gas reserves. Transportation from this interior is linked to Turkestan's capital and ports on the CASPIAN SEA by the Kara Kum Canal and a railroad link that crosses the Amu Darya in an impressive mile-long bridge at Chardzhou. The Amu Darya itself is little used for commercial traffic, since the Aral Sea connects with no other bodies of water, and the river itself is

filled with constantly shifting sandbars and a variety of meanders.

## Amur River

THE AMUR RIVER, in Siberia, springs from the confluence of the Shilka and Argun Rivers east of Lake BAIKAL and flows over 1,800 mi (2,897 km) toward the Tatar Straits, the passage between Sakhalin and the Russian Pacific Coast. With all tributaries, the Amur basin covers nearly 750,000 square mi (1,942,491 square km) of area. The Russian push into the river valley in the mid-17th century resulted in a border clash with the Chinese Empire. The Treaty of Nerchinsk (1689) admitted the territorial sovereignty of the Manchu dynasty over the Amur region for 150 years. The Chinese know the river as the Heilongjiang. In the mid-19th century, the Amur, as the lone river in Siberia that flows eastward to the PACIFIC OCEAN, gained geopolitical significance for the Russian Empire. After the unequal treaties concluded with CHINA in 1850 and 1860, RUSSIA annexed the Amur region.

Russian 19th-century geographers spoke of the Amur as Russia's gateway to the Pacific. Not only is the river abundant with fish, but also the mild climate is appropriate for agriculture (grain, vegetables, fruits). A systematic geographical exploration of the river by the Russians began in 1824 with Grigorii Spasskii's study "Historical and Statistical Notes about Places along the River Amur." In 1846, navigator Alexander Gavrilov sailed to the mouth of the Amur and reported that the river was too shallow for even small ships. This was revised by Gennadii Nevel'skoi's expedition in 1849 that found that the mouth of the Amur was navigable by ships of any size.

The Russian government feared a British occupation of the river mouth and the east Siberian general governor, Nikolai Murav'ev-Amurskii, coined the

Russian geopolitical logic that whoever shall control the mouth shall control Siberia to Lake Baikal. In 1856, the tzarist government declared the Amur region a free trade zone. After the emancipation of the serfs (1861), the government supported the free colonization with tax exemptions. Though some thousands of peasants settled along the Amur, the region remained underpopulated until the modern era.

In view of the illegal migration between 1860 and World War I, the tzarist government founded the so-called Amur Cossack Division, which supervised the border line along the river. In the Russian Civil War (1917–22) Japanese troops occupied the Amur region. Again in the 1930s and in the late 1960s, the Amur became a military trouble spot between the Soviet Union and its East Asian neighbors, JAPAN and China. In the era of Sino-Soviet confrontation, the Soviet government created a frontier ethos that was, at least, reflected by the construction of the BAM (Baikal-Amur-Magistrale). After the breakdown of the Soviet Union in 1989, the Amur region experienced a population outflow to European Russia that resulted in a declining industrial production. Nevertheless, the Amur region seeks economic cooperation with nearby China and facilitates border trade between the cities Blagoveshchensk and Heihe.

## Anatolian Plateau

THE ANATOLIAN PLATEAU is the central upland region of the ancient region of Anatolia, today's TURKEY. The plateau is hemmed in by two parallel mountain ranges, the Taurus to the south, along the Mediterranean coast, and the Pontic Mountains to the north, along the coast of the BLACK SEA. Anatolia has served as a bridge between the civilizations of Europe and Asia for thousands of years, with waves of different cultures taking advantage of this central position

and establishing cities and empires on the plateau. Site of the first large empire of the Western world, the Hittite, dating from the 15th century B.C.E., the plateau was later given its modern name Anatolia, or "rising sun" by the Greeks looking eastward.

Most of the Anatolian Plateau lies at elevations above 1,640 ft (500 m). This mountainous region lies at the center of the Arabian, African, Eurasian, Aegean and Turkish tectonic plates: the resulting landscape is dotted with volcanoes (today extinct) and regular earthquakes. The central plateau is composed of uplifted blocks and downfolded troughs filled by shallow salt lakes. Elevations on the plateau itself range from 1,980 to 3,960 ft (600 to 1,200 m). This increases to the east, where the two mountain ranges, the Taurus and Pontic, join to form the eastern highlands (including the highest mountain peaks in Turkey such as Mount Ararat).

The two largest basins on the plateau are the Konya Ovasi and the basin occupied by Tuz Gölü (Salt Lake)—both drain large inland areas and have no external outlet. Other parts of the plateau are drained either by short rivers that flow south into the Mediterranean, or by several larger rivers (notably the Halys and the Sakarya) that drain northward into the Black Sea. Two extinct VOLCANOES, Erciyes and Hasan, left behind lava flows that have eroded over time to form spectacular landscapes of rock cones and capped pinnacles in Goreme, near Nevsehir. The earth in these areas is colored a variety of grays and reds.

The plateau is mostly dry with a mixture of dark and desert soils. Summers here are hotter and drier than in the rest of Anatolia, but also colder and wetter in the winter, with temperatures averaging freezing and frequent heavy snows. The plateau is mostly covered in STEPPE, with short grasses, bushes and stunted willow trees.

Wooded areas are confined to the northwest and northeast, and cultivation (wheat and barley) is restricted to narrow river valleys. IRRIGATION is practiced where water is available, but a deeply entrenched river course makes it difficult for engineers to raise the water to the surrounding agricultural land. Summer dust storms, locusts, extreme heat, and occasional droughts limit agricultural output. Some areas are cultivated with orchards and vineyards, but for the most part the land is used for grazing. Some larger animals live in the highlands (wolf, fox, bear), but the ubiquitous domesticated Angora goat is everywhere. Stock raising is important and overgrazing has also caused some erosion problems.

The capital of the republic of Turkey was moved to the Anatolian Plateau in 1923. The city of Ankara was chosen as the capital of the new state to remove it from connotations of the imperial capital at Istanbul and to place it in the geographic center of the country. The region is also home to ancient ruins of the Hittite civilization at Çatal Hüyük and to the underground cities of Kaymakli and Derinkuyu, ancient refuges for early Christians. Konya (Roman Iconium) is the region's major cultural center, known for its mosques and "whirling dervishes."

## ancient empires and explorations

SINCE THE BEGINNING of history, human beings have explored the Earth. With the creation of empires, the explorations were often connected to great expeditions made to conquer new territories or to open new commercial roads. The ancient empires and their explorations include the following.

EGYPT appeared as a unified state around 3300 B.C.E. About 3100 B.C.E., Egypt was united under Menes, who inaugurated the 30 pharaonic dynasties in which Egypt ancient history is divided: the Old and the Middle Kingdoms and the New Empire. The Egyptians reached Crete around 2000 B.C.E. and were invaded by Indo-Europeans and Hyksos Semites. They defeated the invaders around 1570 B.C.E. and expanded into the AEGEAN SEA, SUDAN, LIBYA, and much of Southwest Asia, as far as the Euphrates River. It survived as an independent state until about 300 B.C.E.

Sumerians lived in the southern part of Mesopotamia from the time of settlement until the time of Babylonia. The Sumerians inhabited various city-states, each built around a temple dedicated to the god of the city and ruled over by a king, who was tied to the city's religious rites. Discoveries of obsidian from places in Anatolia (modern TURKEY) and AFGHANISTAN,

pearls from Dilmun (now BAHRAIN), and many seals inscribed with the Indus Valley script, suggest a considerable wide-ranging network of ancient trade around the PERSIAN GULF. The Epic of Gilgamesh refers to trade with far lands for goods such as wood that were scarced in Mesopotamia. In particular, cedar from LEBANON was appreciated.

Assyria, a country on the Tigris River, was in the beginning a colony of Babylonia and was ruled by viceroys from that kingdom, founded in 1700 B.C.E. In 1120 B.C.E., Tiglath-Pileser I, the greatest of the Assyrian kings and founder of the first Assyrian Empire, crossed the Euphrates, defeated the kings of the Hittites, conquered Carchemish and advanced on the coasts of the MEDITERRANEAN SEA. In 745 B.C.E., Pul, who assumed the name of Tiglath-Pileser III, directed his armies into SYRIA and took it in 740 B.C.E. Azariah was an ally of the king of Hamath, and thus was obliged by Tiglath-Pileser III to pay him homage and give a yearly tribute. In 738 B.C.E., in the reign of Menahem, king of Israel, Tiglath-Pileser III invaded Israel. The king Assurbanipal entered on a conquering career and, having absorbed Babylon, the kingdoms of Hamath, Damascus, and Samaria, conquered Phoenicia and made Judea feudatory, and subjugated Philistia and Idumea.

Phoenicia was an ancient civilization with its heartland along the coastal plain of what is now Lebanon and Syria. Phoenician civilization was an enterprising maritime trading culture that spread right across the Mediterranean during the 1st century B.C.E. Phoenicians founded independent city-states like Byblos, Tyre, Tripolis, and Berytus, as well as others on the islands and along other coasts of the Mediterranean Sea. This league of ports was then ideally suited for trade between the Levant area rich in natural resources and the rest of the ancient world. Byblos soon became the main center from where they proceeded to dominate the Mediterranean and Erythraean sea routes. Byblos was attacked by invaders, and by around 1000 B.C.E. Tyre and Sidon had taken its place. In the centuries after 1200 B.C.E., the Phoenicians formed the major naval and trading power of the region.

The Phoenicians established commercial outposts throughout the Mediterranean, the most notable being Carthage in North Africa, with others in CYPRUS, Sicily, Corsica, Sardinia, SPAIN, and elsewhere. The Lebanese, Maltese and some Somalians still consider themselves descendants of Phoenicians. Their ships ventured out into the ATLANTIC OCEAN as far as Britain, where the tin mines in modern Cornwall provided them with impor-

tant material. They also sailed south along the coast of Africa. A Carthaginian expedition led by Hanno the Navigator explored and colonized the Atlantic coast of Africa as far as the Gulf of Guinea, and a Phoenician expedition sent out by Pharaoh Necho II of Egypt even circumnavigated Africa.

## GREEK EMPIRE

Greece is a region on the south of the European continent. It is defined by mountains, surrounded on all sides except the north by the sea, and endowed with large and small islands. The Ionian and AEGEAN SEAS and the many bays allowed the Greeks to prosper in maritime commerce and to develop a culture that was inspired from many sources, both foreign and local. The Greek world spread far beyond Greece itself, including many settlements around the Mediterranean and BLACK SEAS. The mountains, which served as natural obstacles and boundaries, imposed the political character of Greece.

From early times the Greeks lived in independent communities isolated from one another by the landscape. Later these communities were organized into CITY-STATES. The mountains prevented large-scale farming and prevented the Greeks to look beyond their borders to new lands where fertile soil was more abundant. The Greeks started to sail the seas to conduct commerce since very ancient times and reached the Pillars of Hercules, but the great movement of expansion of Greek people was between the 8th and 7th centuries B.C.E., enlarging geographical knowledge. These travels that prepared the Greek colonization of Mediterranean area were true explorations. The result was important for the knowledge of the entire Mediterranean Sea and Black Sea and the surrounding area, into the internal mountains of Asia and eastern Africa.

The expansion of Alexander the Great's kingdom started in 336 B.C.E., when he succeeded his father to the throne of Macedonia. After that, Alexander began a military expedition with the intention of conquering the Persian territory in Asia Minor and set Egypt free, becoming the emperor of a new huge realm. At its greatest extent, this empire covered over 3,000 mi (4,828 km) from Greece to INDIA, enclosing Egypt and Persia, up to the river Indo. The capital of this dominion was Alexandria in Egypt, founded about 331 B.C.E. During army marches, country by country, several teams of geographers, botanists, and other men of science collected information and specimens for Aristotle, the mentor of Alexander. While a historian kept records of the march, cartographers made maps that

served as the basis for the geography of Asia for centuries.

To administer his empire, Alexander adopted a type of monarchy already used in the Persian Empire, introducing in his court also some elements like uniforms and customs from the Persian culture. This kind of government did not agree with the different populations under Alexander's control, and they rebelled. Alexander tried to stop these tumults by proclaiming and encouraging the formation of a hegemony among different people living in his kingdom. This project died with its promoter, Alexander, starting an age of war among his successors and marked the beginning of the decline of this empire. After 40 years of conflict, the conquered territory was divided into three regions: Egypt went to the Ptolemys, the kingdom of Syria submitted to the Seleucids, and the Antigonids took Macedonia. These new realms, so-called Hellenistic, brought the Greek culture into Asia and Egypt, creating times of prosperity for all thanks to a large availability of precious metals and other types of goods, mainly treasures from the Persian War. New commerce routes were established and in Alexandria, the largest library of the ancient world was built. The campaigns of Alexander in Libya and in Asia reached Turkestan and India, revealing a lot of new great mountains and large deserts, the great rivers of India, and the Southern Ocean (sailed for the first time by the fleet of Nearco from the Indo to the Euphrates).

## ROMAN EMPIRE

The power of Rome (founded in 754 B.C.E.) started with its expansion in Italy and in Europe and finally in the Mediterranean area and farther. After the kingdom and the republic, the Roman Empire started with Augustus in 27 B.C.E. The greatest expansion was during the reign of Trajan (98–117), when he conquered Dacia. In this age, the Roman Empire extended from Spain to the West Pontus and North Arabia to the east, from Britannia to the north, and to the North African coasts in the south. Constantine transferred the capital of the empire in Byzantium, and his heirs divided the empire into two parts. The empire died in its occidental form in 476, when Odoacre deposed the last emperor and transferred the power in Constantinople. The eastern half of the empire remained the heartland of the Roman state until 1453, when the Byzantine Empire fell to the Ottoman Turks.

The administration of the Roman Empire was divided in provinces. The number and size of provinces changed according to internal Roman politics. Under

the Roman republic, the governor of a province was appointed for a period of one year. At the beginning of the year, the provinces were distributed to future governors by lots or direct appointment. During the empire, the biggest or more garrisoned provinces were subdivided into smaller provinces in order to prevent a situation where a unique governor held too much power, thus discouraging ambition for the imperial throne itself. With the formation of the principate after the civil wars ended the Roman republican period, Augustus retained the power to choose governors for the provinces in which he and his successors held supreme military and administrative control. Thus, the more strategically critical provinces, generally located along the contested borders of the empire, became imperial provinces. The remaining provinces were maintained as senatorial provinces, in which the senate had the right to appoint a governor. During the empire of Diocletian, the diocese was created, a large administrative unit made up of up to 16 provinces. The empire was separated into 12 (or later, 15) dioceses. Each diocese was governed by a praetor vicarius who was subject to the prefect.

Everywhere the Roman Empire extended, great architectural structures were built. A great road network connected the entire Roman Empire, facilitating trade and exploration. From the second half of the 2nd century B.C.E., until the first century, the military campaigns that consolidated the Roman Empire helped the progress of geographic knowledge. The Greeks, as a mainly seafaring people, explored the coastlands; thanks to the Romans, knowledge of the inside lands also became known. The Alpine regions of the Gallia, the interior of Iberia, and Britain and Germany were finally explored. North African lands were explored, from Ethiopia and the Nile Valley beyond the confluence of the two principal branches (during the empire of Nero), to Libya, where military expeditions scouted the middle of the SAHARA DESERT and the ATLAS MOUNTAINS in MOROCCO.

In Asia, the mountainous regions of ARMENIA, Arabia, and the lands beyond the Pontus were explored. The knowledge about the Torrid Zone of the world was revised with the discovery of the existence of Ethiopic people living beyond the African desert. The existence of nomad people living in northern Europe, where Romans thought lived the fabulous Iperboreans, was also proved.

## Andes

THE ANDES IS A mountain system in South America. The mountains form the “backbone” of South America, stretching from the Caribbean coast along the western side of the continent to its southern tip. The name *Andes* probably derives from either Quechua or Aymara, the two principal Native American languages of South America. Plate-tectonic forces during the Cenozoic Era created the Andes. The mountains are a result of a collision between the continental South American plate and the oceanic Nazca plate that created high peaks and steep slopes. The region is still tectonically active, as earthquakes are common and there are frequent volcanic eruptions. The Andes sometimes serve as a geographic boundary that divides countries, as is the case of the border between ARGENTINA and CHILE. The mountains also divide regions within individual countries.

The highest peaks are found in Argentina, PERU, and ECUADOR. ACONCAGUA MOUNTAIN in Argentina is the highest peak in the Western Hemisphere at 22,834 ft (6,960 m). The lowest peaks are found in the southern and northern extremes. The Andes are widest in BOLIVIA, where there are actually two distinct ranges known as the Cordillera Occidental (Western Range) and Cordillera Oriental (Eastern Range).

Much of the Andes lies in the tropics. However, altitude is generally more of a determining factor than latitude. Indeed, there are even glaciers and snow near the equator. Climate and vegetation are also determined by altitude. Furthermore, elevation affects temperatures, even at the same latitude. Temperatures tend to decrease about 3.7 degrees F for every 1,000-foot (305 m) increase in altitude. For example, Quito, Ecuador, located high in the Andes, has an average annual temperature of 54.6 degrees F (12.5 degrees C). Guayaquil, Ecuador, located at almost the same lati-

tude, but on the coast, has an average temperature of 78.2 degrees F (25.6 degrees C).

In the tropics, different elevations are divided into several distinct categories. Altitudes up to about 3,000 ft (914 m) are referred to as *tierra caliente* (hot country). Elevations located between 3,000 and 6,000 ft (914 m and 1,829 m) are called *tierra templada* (temperate land). *Tierra fria* (cold land) can be found at altitudes of 6,000 to 12,000 ft (1,829 m to 3,657 m). Finally, regions above 12,000 ft (3,657 m) are classified as *tierra helada* (frozen land).

Much of the Andean region is arid, including the Atacama Desert. On the western side of the Andes, streams do not have well-defined headwaters. In contrast, on the eastern side, there is more rain and more significant headwaters. Two of South America's major river systems—the AMAZON and the Orinoco—both begin in the Andes.

The high altitudes of the Andes make human settlements in the region difficult. Nevertheless, shepherds in southern Peru have lived permanently at altitudes above 17,000 feet (5,181 m). Temporary mine workers have lived at altitudes around 19,000 ft (5,791 m). In general, the southern Andes are sparsely populated. There is a heavier concentration of people on the plateaus from Bolivia to COLOMBIA. Many people in countries such as Peru and Bolivia reside above 10,000 feet (3,048 m). Some of the continent's largest cities are located on these central Andean plateaus, including Santiago (Chile), Lima (Peru), Quito (Ecuador), and Bogotá (Colombia).

Before 600 C.E., human beings concentrated along the PACIFIC OCEAN coast rather than in the Andes. After that date, a number of advanced Native American civilizations established themselves in the Andean highlands. The two largest states before 1000 C.E. were Tiahuanaco, south of Lake TITICACA, and the Huari, centered near modern-day Ayacucho. After 1000, the most significant group was the Chimú, with its capital at Chanchán. The Chimú kingdom lasted until the 15th century, when the Incas conquered it. The great Inca Empire, with its capital at Cuzco, dominated much of the region during the 15th and 16th centuries.

In the 1530s, Spanish conquerors subdued the Incas, bringing the Andes into Spain's New World empire. The Spanish often used systems of forced Native American labor to work in Andean silver mines. The native inhabitants did not always readily accept Spanish rule. In the 18th century, there were more than 100 native rebellions, including the great uprising led by José Gabriel Condorancú in 1780. In the 19th cen-

Because of the range's length, position, and curvature, the Andes Mountains are called the "backbone of South America." The Andes run through the countries of Colombia, Ecuador, Peru, Bolivia, Chile, and Argentina and reach heights above 20,000 ft or 6,095 m.

tury, the Spanish colonies achieved their independence. Parts of the Andes can be found in VENEZUELA, Colombia, Ecuador, Peru, Bolivia, Chile, and Argentina.

Agriculture in the Andes has always been difficult. Crop yields are generally low. Many areas are dry or receive irregular rainfall. Temperatures are often too low for agriculture. Therefore, most agricultural production is for local consumption rather than for export. However, some products grow well enough to serve as export products. Colombian coffee is world renowned. Illegal drug traffickers utilize Andean coca to produce cocaine for export around the world.

The Andes is one of the world's most important mining regions. Among the most mined minerals are gold, silver, copper, tin, platinum, and emeralds. Silver in particular played an important part in the Spanish colonial period. Potosí, located in modern-day Bolivia, was the richest silver mine in the world and large boom town grew up around it. Along the eastern side of the Andes, there are substantial deposits of oil.

The Andes have long been a barrier to trade and communications in South America, especially to east-west travel. Centers of agricultural and mining production have generally been located far from ports on the coasts. People in the Andes long depended on pack animals to transport goods through the mountains. Railroad and road construction has often been difficult, though air travel has made the region more accessible.

## Andorra

**Map Page** 1131 **Area** 183 square mi (468 square km)  
**Capital** Andorra la Vella  
**Population** 69,150 **Highest Point** 9,722 ft (2,946 m)  
**Lowest Point** 2,772 ft (840 m) **GDP per capita** \$19,000  
**Primary Natural Resources** hydropower, timber.

ONE OF THE WORLD'S true curiosities, the sovereign coprincipality of Andorra retains independent status which, according to local history, was granted in the 9th century by Charlemagne for the people's valiant services to him against the Moors. Consisting of the upper valleys of the river Valira, this tiny country is nestled among the high mountain passes of the Pyrénées between FRANCE and SPAIN. Only 2.5 times the size of Washington, D.C., it is one of the smallest countries in the world. What makes Andorra truly curious, however, is its unusual status as a coprincipality, though without a local prince; instead, it is governed jointly by the republic of FRANCE and by the Bishop of Urgell, a small town a few miles to the south in Spain. The French president and the bishop act as coprinces only nominally, however, and since 1993 the country has been entirely sovereign and self-ruling.

### PEAKS AND VALLEYS

Andorra is located between the French department of Ariège, in the region of Midi-Pyrénées, and the Spanish province of Lérida (or Lleida) in the region of Catalonia. Consisting of high mountain peaks and narrow valleys, the elevation of Andorra ranges from 6,500 to 10,000 ft (2,000 to 3,000 m). The climate is fairly severe, restricting vegetation to minimal mountain scrub: One suggestion of the origin of the name *Andorra*, is that it comes from a local term for "shrub-covered." But this climate provides excellent high mountain pastures for sheep and cattle and is also a great attraction for skiers from all over Europe. The economy runs mostly on tourism, with numerous summer and winter resorts, and also as a duty-free shopping center. Much of Andorra remains rural. Most of its inhabitants live in one of six main villages, raise their herds of sheep or cattle, and manage small farms, raising rye, wheat, barley, oats, and vegetables. There are also some fruit orchards and vineyards. Most of the population lives in and around the capital, Andorra la Vella, where there is some light manufacture, notably cigarettes, sandals, and anisette liqueur.

The coprincipality has been jointly ruled since a treaty in 1278 between the Count of Foix and the Bishop of Urgell. At that time, there were several small states between France and Spain; the unusual thing is that this one survived into the 21st century. The pass of Port d'Envalita (7,943 ft or 2,407 m) has served as a major route between Toulouse, France, and northern Spain since ancient times. While the status of the bishop remained the same, the Counts of Foix eventu-

ally died out and the title was absorbed by the king of France in the 17th century. After the French Revolution, the post naturally fell to the president of the republic. In 1993, Andorrans voted in favor of a new constitution that, while retaining the honorific position of the coprinces, gives Andorra complete sovereignty and control over its affairs, both internal and external. It has been a member of the EUROPEAN UNION (EU) since 1990, uses the euro, and became a full member of the United Nations in 1994. But Andorra's position as a free-port also brings with it the associated problems of smuggling and money laundering, the subject of an accord settled between the five European microstates and the EU in 2003.

## Angola

**Map Page** 1116 **Area** 481,351 square mi (1,246,700 square km) **Population** 12,386,000 **Capital** Luanda **Highest Point** 8,594 ft (2,620 m) **Lowest Point** 0 m **GDP per capita** \$865 (2002) **Primary Natural Resources** petroleum, diamonds, natural gas.

A COUNTRY LOCATED along the southwest coast of Africa, the republic of Angola is a vast territory divided into 18 provinces, one of which, Cabinda is an exclave within neighboring CONGO. The Berlin Conference of 1885–86 determined the current borders with the Republic of the Congo, Democratic Republic of the CONGO, ZAMBIA, and NAMIBIA. Portuguese is the official language, but Umbundo and several other African languages are also spoken in rural areas. Angola has a semi-presidentialist system, with the president being both chief of state and head of government.

From a coastal plain, the land rises in stages toward the high interior plateaus, covered mainly with grasslands and bushes. There are tropical forests in the north, and a rocky desert occupies the southwest cor-

ner. Angola's climate is tropical, humid in the north with a cool dry season (May to September) and a warm rainy season (October to April), and becomes semiarid in the south.

## HUMAN GEOGRAPHY

Humans have lived in the area that is now Angola since prehistoric times, with Bantu-speaking peoples settling there about 2,000 years ago. The Portuguese arrived in the 1480s and built fortresses and outposts along the coast. In the following three centuries, Angola became a primary source of slaves for the Americas, especially for BRAZIL. In the 20th century, thousands of Portuguese moved to Angola, seeking a better life in a land of great natural resources and potential. In 1975, Angola gained independence from Portugal. War has been the norm in the last 40 years, costing more than 1.5 million lives, leaving the economy in disarray, and causing destruction of basic infrastructures and widespread presence of post-battle land mines.

Ethnicity plays an important role in the country, with most of the population of Bantu origin. Other groups include the Ovimbundu, the Mbundu, and the Kongo. The capital and largest city is Luanda (3 million people), and main cities include Cabinda, Benguela, Lobito, and Lubango. The majority of the young population lives in rural areas and depends on subsistence agriculture. Life expectancy is low in this African country.

Angola has enormous natural resources, among them petroleum off the northwest coast, and diamonds in the northeast. Oil contributes with almost half the GDP and more than half of exports. Main economic activities are mining, logging, and farming. Agricultural production includes bananas, cassava, coffee, sugarcane, sisal, corn, cotton, and manioc, but much of the food is imported. The rich fisheries nurtured by the Benguela current along the 994-mi (1,600-km) coast are still underexploited. The country also has significant hydroelectric potential, since the central highlands are the source of many important rivers, such as the Cuanza, Cunene, and Cubango.

SERGIO FREIRE  
PORTUGUESE GEOGRAPHIC INSTITUTE

## Anguilla

ANGUILLA IS ONE of the smallest and least developed islands in the CARIBBEAN SEA. It was administered as a British colony along with SAINT KITTS AND NEVIS until 1971. Its inhabitants did not wish to remain a dependency of its larger neighbors when they achieved independence in 1983, and Anguilla opted instead to retain its status as an overseas dependency of the UNITED KINGDOM (UK).

Unlike St. Kitts and Nevis, Anguilla is not made up of volcanic peaks with fertile soil and abundant rainfall, but instead consists of flat, semiarid coral and limestone formations that are generally unproductive for any sort of agriculture. This marks the main contrast between the two arcs of the Lesser Antilles: the older arc, further to the east, was once volcanic but sank beneath the sea; the tips became covered in limestone and coral and slowly reemerged from the sea, but rarely higher than 330 ft (100 m). This is the case for Anguilla and its closest neighbors, the French dependencies of St. Martin and St. Barthélemy to the south and the British Virgin Islands to the west.

Anguilla also includes some smaller islands, Scrub and Dog, and the Prickley Pear Cays, plus the tiny island of Sombrero, with a lighthouse important for regional shipping. Anguilla is located on the strategic Anegada Passage, a primary shipping route between the ATLANTIC OCEAN and the PANAMA CANAL, but lacking any substantial port or harbor, it has been unable to take advantage of this position. The terrain is mostly rocky, with sparse scrub and few trees. Some areas do produce small quantities of tobacco and vegetables or support cattle. Other areas are dedicated to commercial salt manufacture through evaporation ponds. The economy relies instead on tourism—with its excellent beaches and reefs—plus boat building and offshore financial services, though none of these industries produces sufficient revenue to allow the country to sever its ties with the UK, which provides heavy subsidies.

Originally named by the Spanish *anguilla* or “eel” because its long narrow shape, the island had no interest for the gold-seeking Spaniards. It was not until the 1650s that the first settlers claimed the island for Britain. Administered with St. Kitts and Nevis from 1825, it never developed a sugar economy like theirs, and when the three islands achieved internal self-rule in 1967, Anguilla declared its intentions to separate from the other two (located over 62 mi or 100 km to the southwest). The government, with British support, is attempting to develop its tourism industry but has been

hampered by successive hurricane damage, notably Hurricane Luis in 1995.

## Antarctic Circle

THE ANTARCTIC CIRCLE is an imaginary line located at 66.5 degrees south latitude or 23.5 degrees northward of the South Pole. It marks the southernmost location where the sun can be seen on June 22 (the Southern Hemisphere’s winter solstice) and the northernmost location where the midnight sun is visible on December 21 (the Southern Hemisphere’s summer solstice).

On June 22 and again on December 21, the circle of illumination, formed by the sun’s rays striking the Earth, extends from the edge of the Antarctic Circle in the south to the ARCTIC CIRCLE in the north. On June 22, the area within the Antarctic Circle experiences 24 hours of darkness and on December 21 it receives 24 hours of sunlight. The name *Antarctic* comes from the Greek *arktos*, or “bear,” in reference to the area’s position below the Great Bear constellation (Ursa Major).

British naval captain James Cook was the first to cross the Antarctic Circle in 1773. Exploration of the region within the Antarctic Circle resumed in 1820 when the explorer Fabian Gottlieb von Bellingshausen received support from Russian Tzar Alexander I to explore the south polar region. On January 26, 1820, Bellingshausen’s ship, the *Vostok*, crossed the Antarctic Circle, becoming the first to do so since Cook in 1773. Other early explorers of the region include English naval captain Edward Bransfield and American seal hunter Nathaniel Palmer.

OKLAHOMA STATE UNIVERSITY

## Antarctica

THE WORLD'S fifth-largest continent, Antarctica is home to the South Pole. This continent of almost 98 percent ice and 2 percent barren rock holds the distinction of being the coldest, windiest, driest, and highest continent. Antarctica covers some 5.4 million square mi (14 million square km), and has no indigenous people, but seasonal staff from 1,000 to 4,000 people. The continent's highest point is Vinson Massif at 16,066 ft (4,897 m) and lowest point is the Bentley Subglacial Trench at -8,382 ft (-2,555 m).

Frequent, gusty winds blow from the interior sections toward the coast, and blizzards are common along the foot of the plateau. Volcanoes are scattered along areas of West Antarctica, and large icebergs frequently break off from the ice shelf. Cold temperatures are spread across the continent. The higher elevations of East Antarctica provide the coldest temperatures. A more moderate climate is found on the Antarctic Peninsula, where high temperatures average closer to freezing.

Although the climate is incredibly harsh and dry, plant species, albeit small in size, are numerous. Hundreds of algae species are scattered across the land, as well as around 100 species of moss, 350 species of lichen, and 2 grass species. The subantarctic islands surrounding Antarctica have a wider range of flora. About 45 bird species populate the area south of the Antarctica Convergence, and a few penguins and petrels actually live on the continent. The waters surrounding Antarctica are full of seabirds, fish, seals, and whales.

The continent remained untouched by humans until the 19th century. In 1773, British sea captain, James Cook was the first to cross the ANTARCTIC CIRCLE, but never saw any of the landmass. Almost five decades later, in 1819, the Russian naval officer Fabian von Bellingshausen discovered some of the islands. However, it was not until a year later that British naval officers William Smith and Edward Bransfield discovered the landmass. A few months later in November 1820, an American sealer, Nathaniel Palmer, also discovered the continent.

In 1822, another American sealer, Captain John Davis, became the first person on record to land on the continent. For the remainder of the decade, British, French, and American expeditions navigated the land and proved that Antarctica was indeed a continent. In 1838, Lt. Charles Wilkes of the U.S. Navy explored some 1,200 miles of the Antarctic Peninsula.

From the late 19th century until 1916, explorers across the world were engaged in a race to see who would first reach the South Pole. In 1902, the British explorer Captain Robert Falcon Scott led an expedition to Antarctica with Ernest Shackleton and Edward Wilson. They were forced to abandon the adventure because of the harsh conditions and scurvy. Five years later, Shackleton attempted to travel to the South Pole, but within 97 mi (156 km) of the South Pole, his supplies dwindled and he had to abandon the effort.

On December 17, 1911, the Norwegian explorer Roald Amundsen and his team of four were the first to reach the heralded South Pole. Almost one month later, on January 18, Captain Scott and his team successfully reached the South Pole but found the claim marker the Norwegians had left. The Norwegians left the ice continent ahead of the British explorers and from Tasmania sent a telegram proclaiming to the world that they had found the South Pole. Scott and his crew, unfortunately, died from the harsh conditions and lack of food, while heading back to the coast. No humans set foot on the South Pole again until 1956.

From July 1957 to December 1958, 12 nations established over 60 polar stations in Antarctica. In 1959, the Antarctica Treaty was created by the nations having an interest in the continent. It outlined certain conditions in maintaining the natural environment, and

*A photo taken from space by NASA focuses directly on the South Pole on the continent of Antarctica.*

stated that the land could only be used for peaceful purposes. Nuclear testing was outlawed as well as dumping nuclear waste. By 1961, the terms of the treaty were made into international law, and since then, seven nations' claims of sovereignty of the Antarctic have been suspended. Dotted across the continent are polar stations; it is obvious that Antarctica has become a haven for explorers and scientists.

Antarctica remains a continent untouched by any industrial machine. However, the effects of overall global pollution are evident in the sky above. The ozone hole over the continent has expanded, and ice shelves have begun to disintegrate. In 1997, a Norwegian, Boerge Ousland, became the first person to cross Antarctica alone. The continent remains a mysterious and beautiful area for scientists conducting experiments and for explorers in testing their endurance in some of the harshest conditions on Earth.

## Antigua and Barbuda

**Map Page** 1137 **Area** 173 square mi (443 square km)  
**Capital** Saint John's **Population** 67,897 **Highest Point** 1,326 ft (402 m) **Lowest Point** 0 m **GDP per capita** \$11,000 **Primary Natural Resources** pleasant tropical climate.

ANTIGUA WAS ONE of the primary British colonies in the CARIBBEAN SEA and remains a leader among the Leeward Islands (from the Virgin Islands to GUADELOUPE). Along with the nearby island of Barbuda, and the much smaller island of Redonda, Antigua became

independent in 1981 but retains close links with the UNITED KINGDOM (UK) and its commonwealth.

The islands are located in the northern part of the Lesser Antilles chain, approximately 80 km (50 mi) east of SAINT KITTS AND NEVIS, and the same distance north of the French island Guadeloupe. Unlike these neighbors, none of the three main islands are volcanic and mountainous but are low-lying coral and limestone formations. Antigua was one of the first islands encountered in the voyages of Christopher Columbus, who named it Santa María de la Antigua. The Spanish and French attempted to set up colonies but were discouraged by lack of fresh water and attacks by native Carib peoples. English planters established a permanent settlement in the 1630s and within a few decades had completely deforested the island, eradicated any native population, and repopulated it with large numbers of African slaves. The chief city, St. John's, was one of the region's most prosperous ports in the 18th century as a center for the sugar trade but declined after the abolition of slavery in 1834. Nelson's Dockyard, on the south side of the island, remains a testament to this prosperity and has been a national park since the 1980s. Sugar remained the island's major product until the 1960s but has now mostly disappeared.

Barbuda, 30 mi (48 km) to the north, was never developed as a commercial sugar producer, and it retains a separate identity from its larger, more populous partner, occasionally even voicing a desire for autonomy or independence from Antigua. Most of its 1,500 residents live in the only settlement, Codrington, named for Antigua's first major planter, who leased Barbuda to raise provisions and conduct slave-breeding experiments. Barbuda is also known among scuba divers and tourists for its numerous sunken ships and untouched reefs.

The tiny volcanic rock of Redonda, only .5 square mi (.8 square km), is located 35 mi (56 km) to the southwest of Antigua. It is populated only by goats, seabirds, and lizards but is the seat of the fabulous "Kingdom of Redonda," a literary-review group (mostly based in LONDON, England) established in the early 20th century.

The chief natural resource of Antigua and Barbuda is the climate: The tropical marine climate, perpetually sunny skies (bad for crops, good for tourism), and 365 white sandy beaches (one for each day of the year) make these islands one of the most popular tourist destinations. Together with historical settings and abundant duty-free shops in St. John's, the island's tourist

economy has given Antigua one of the highest per capita incomes in the Caribbean.

SMITHSONIAN INSTITUTION

## antipode

DURING THE TIME of Plato and Aristotle (circa 390 B.C.E.), the term *antipode* was used in reference to a natural balance thought to be sustained by the existence of a continent south of the equator, equal in size to the northern continent. Ptolemy (100–170 C.E.) described this southern landmass as Terra Australis Incognita (unknown southern lands).

In contemporary use, the term describes a point on the opposite side of Earth from another location. Antipodes are most often expressed as latitude/longitude coordinates. It is possible to compute the antipode for a given location by subtracting 180 from the location's longitude and changing latitude from degrees north to degrees south or vice versa. For example, the geographic center of TAIWAN is located at 121 degrees east longitude and 24 degrees north latitude. By subtracting 180 from 121 for a longitude of 59 degrees south and changing 24 degrees north to 24 degrees south, the antipode of Taiwan can be identified as being within the country of PARAGUAY in South America. Measured in great circle distance, antipodes are the farthest place on the world's surface from each other. A true circumnavigation of the world requires a traveler to pass through at least two points that are antipodean to each other. Some examples of true (antipodal) circumnavigations include Ferdinand MAGELLAN's 1522 expedition in his ship *Victoria* and Sir Francis Drake's 1580 journey in the *Golden Hind*.

## Appalachian Mountains

THE APPALACHIAN Mountains of eastern North America comprise a north to south-trending range that extends for 1,600 mi (2,500 km) from the Gaspé Peninsula in Atlantic Maritime CANADA to northern ALABAMA in the UNITED STATES. Uplifted by the collision of continents ancestral to North America and Africa 270 million years ago, the Appalachian Mountains are the oldest mountain range in North America.

The Appalachian Mountains consist of a range of landforms from four physiographic provinces. The New England Province consists of rolling coastal lowlands and rugged interior highlands—like the White Mountains of NEW HAMPSHIRE and MAINE and the Green Mountains of VERMONT—of northern New England and Canada. The Ridge and Valley Province consists of long linear ridges separated by valleys with trellis drainage patterns. The valleys are rich in limestone that dissolves to produce sinkholes and underground caverns, producing KARST topography. The Ridge and Valley Province extends from NEW YORK to Alabama. The Blue Ridge Mountain Province extends from south-central PENNSYLVANIA to northern GEORGIA and is a rugged region of high relief with terrain that ranges from narrow ridges with steep slopes to broad mountains. The Appalachian Plateau (known as the Allegheny Plateau in the north and the Cumberland Plateau in the south) is a well-dissected plateau landscape with deeply eroded, dendritic drainage patterns. The Appalachian Plateau extends from New York to KENTUCKY. The northern Appalachian region from Canada to portions of northern Pennsylvania and NEW JERSEY was glaciated until 10,000 years B.C.E.

Elevation tends to increase from north to south in the Appalachian Mountains. In the north, the plateaus and low rounded mountains of the Gaspé Peninsula (the Shickshock Range) may exceed 4,000 ft (1,200 m) in elevation. Seven peaks in New Hampshire's Presidential Range exceed 5,000 ft (1,500 m). Mount Washington, at 6,288 ft (1,886 m), is the second-highest Appalachian peak. Elevation decreases somewhat in the central Appalachians, where ridges and peaks—like the Allegheny Mountains in Pennsylvania and VIRGINIA—generally average 3,000 ft (900 m). Elevations over 5,000 ft (1,500 m) begin in the Blue Ridge Mountains of southwestern Virginia, like Mt. Rogers at 5,729 ft (1,718 m) and Pine Mountain at 1,658 m (5,526 ft) and eventually exceed 5,526 ft (1,800 m) in the Great Smoky Mountains of eastern TENNESSEE and western NORTH CAROLINA. The highest peak in the Ap-

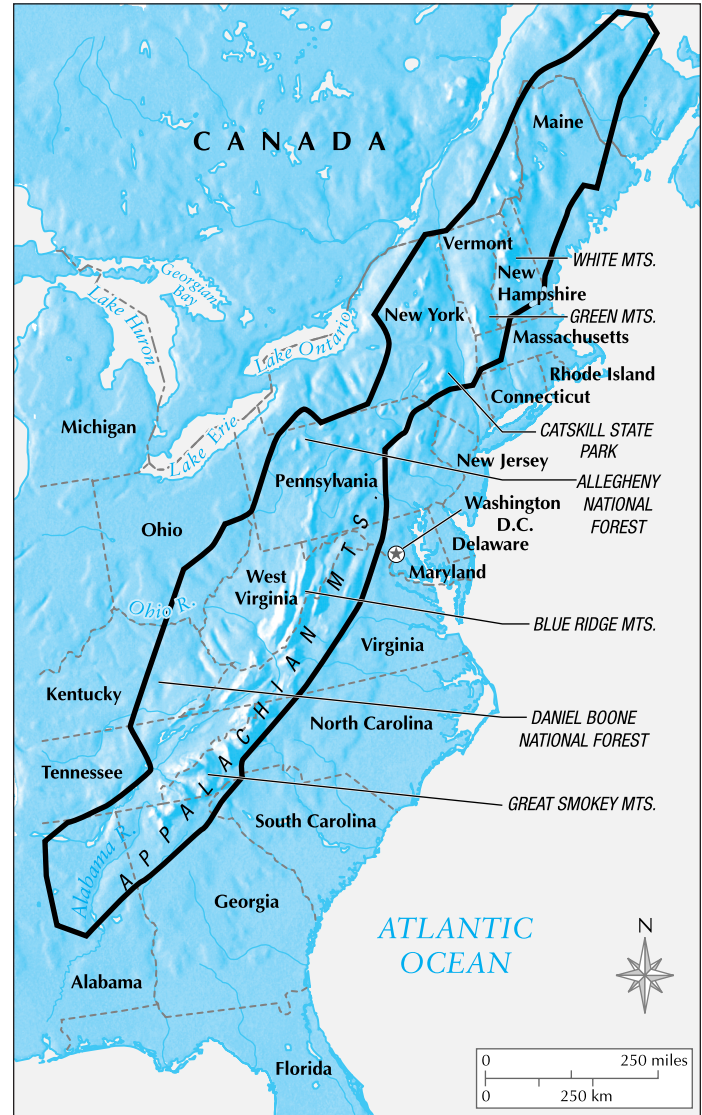

palachians (and the eastern United States) is Mt. Mitchell in the Black Mountains of North Carolina at 6,684 ft (2,037 m).

The climate of the Appalachian Mountains varies with latitude and elevation. Average annual temperature for Canada's Gaspé Peninsula is approximately 38 degrees F (3 degrees C). Annual precipitation averages 35 in (89 cm) in inland areas but may exceed 58 in (147 cm) along the coast. In the central and southern Appalachians, average annual temperatures may range from 50 to 64 degrees F (10 to 18 degrees C), respectively. Average annual precipitation ranges from 35 in (89 cm) in valleys of the central Appalachians to over 78 in (198 cm) in the high peaks of the southern Appalachians, the highest precipitation in the eastern United States.

The biological diversity of the Appalachian Mountains is rich and diverse, a product of varied climate, topography, and glacial history. In the Gaspé Peninsula and the high peaks of the Presidential Range, the summits are treeless and the vegetation is alpine, dominated by low-stature perennial herbs, shrubs, and graminoids and numerous lichens and mosses. Boreal species such as caribou occur in Canada's Shickshock Range and historically occurred in northern New England. Northern Appalachian forests include spruce-fir forests dominated by balsam-fir and red spruce and northern hardwood forests dominated by sugar maple, American beech, and yellow birch. Oak forests, dominated by northern red oak and white oak, become more common in the central Appalachians, particularly on drier slopes. The species-rich mixed mesophytic forest, with over 158 tree species, reaches its greatest development in the southern Appalachians. The southern Appalachians are also the world's center of diversity for the lungless salamanders, harboring 54 species. Many boreal species, like the northern flying squirrel and red spruce, also occur at high elevations in the southern Appalachians, relict survivors of the glaciation that drove them southward.

The Appalachian Mountains are rich in natural resources, particularly minerals and forest products. Coal, both anthracite and bituminous, is abundant in the Appalachians, particularly in the Appalachian Plateau, where oil and gas production is also centered. Limestone is quarried in the karst landscapes of the Ridge and Valley.

## aquifer

AN AQUIFER IS a subsurface structure or formation that provides a sufficiently permeable condition to yield significant quantities of water to wells and springs. Soil water movement is determined by two factors: porosity, which is the ability to hold on to water particles, and permeability, which is concerned with movement. The word *aquifer* comes from two Latin words: *aqua*, or “water,” and *ferre*, “to bear or carry.” Aquifers literally carry water underground.

Precipitation or meteoric water migrates its way downward through the pores or cracks in the soil. Beneath the soil surface is the zone of aeration in which the smaller openings contain a little water and the larger spaces usually contain air. Often soil particles are thinly covered with hygroscopic water, while capillary water is held close to the surface for plant needs. Excess water will infiltrate by gravity to a point where all the spaces are filled with groundwater, which begins the zone of saturation. The top of this layer is called the water table and it will fluctuate depending upon precipitation or draw down.

Aquifers are moderately to highly permeable layers of rock in which groundwater is stored or through which it moves. The formation may be a layer of gravel or sand, a layer of sandstone or cavernous limestone, a rubbly top or base of lava flow, or even granite fractured by ancient ice sheets. Some rock, such as clay or solid granite, may have only a few hairline cracks through which water can move, making them poor aquifers. In terms of storage at any one given time, groundwater is the largest single supply of fresh water available for use. It is estimated that it is more than 30 times greater than all the water stored in streams, rivers and freshwater lakes, yet most of it is not easily accessible. The largest aquifer in the UNITED STATES is the Ogallala, which underlies the land from SOUTH DAKOTA to northern TEXAS.

Rainwater that migrates downward directly to the water table creates an unconfined aquifer, which may be shallow and therefore susceptible to contamination from industrial landfills, agricultural chemical runoff, sewer leakage, faulty septic tank operation, or even salt-water intrusion in coastal areas. A confined aquifer occurs when water is stored beneath a blocking stratum or aquiclude that stops the direct movement of gravitational water to it, allowing water to migrate over long distances, taking years or even centuries.

The quality of groundwater is determined by the depth of the aquifer as bacterial or human pollution

can be screened out by the rocks and soil. Water from a confined aquifer will tend to be freer of dangerous materials.

However, water is a solvent and may also have dissolved minerals. The most likely of these are sodium, calcium, magnesium, potassium, chloride, bicarbonate and sulfate, which are picked up in its movement. Water typically is not considered desirable for drinking if the quantity of dissolved minerals exceeds 1,000 milligrams per liter. Water that is pumped or released from a confined aquifer will rise to a level called the piezomatic surface, which is dictated by the pressure. When pressure forces flowing water to the surface, it is called an artesian well. The largest of these formations is Australia's Great Artesian Basin.

## Arab geographers

IN THE MIDDLE AGES, the Arabs, inspired by Mohammed's faith, conquered the FERTILE CRESCENT, North Africa, southern SPAIN, and much of Central Asia, including IRAN and AFGHANISTAN. Arriving from the deserts of Arabia with a rich linguistic tradition but few material possessions, they soon were introduced to the ancient thought of INDIA, Persia, and GREECE. Within a century, the philosophy and sciences of these older civilizations were translated into Arabic, making it possible for books to be read from Spain to India. In addition, soldiers, sailors, merchants, and travelers from Spain to CHINA were to add information that developed Arab geography. Included in the medieval Islamic reception of these older scientific teachings were the works of geographers. Greek thought called the description of the Earth's features, with the location of people and living things, *geographia*. It was a combination of natural philosophy (science still not differentiated from more speculative philosophical ideas), astronomy, histories, cartography, and travel reports.

Many Greek thinkers, from the pre-Socratic philosophers to the great Hellenistic writers, had contributed to *geographia*, as it was received by the Arab geographers. These included Homer, Anaximander of Miletus, Xenophon, Herodotus, Arrian, Plato, Aristotle, and many others. The main contributors all wrote books specifically about geography. Eratosthenes, the librarian at Alexandria (Egypt), wrote a *geographia* and contributed the use of meridian lines. Poseidonius of Rhodes wrote a geography and accurately calculated the size of the Earth. Strabo wrote *Geographica* to describe in many volumes the MEDITERRANEAN SEA, its adjacent lands, and more. Claudius PTOLEMY, a Greco-Egyptian, wrote *Guide to Geography*. It was the most scientific and thorough geography work of ancient times. He located places with longitude and latitude, discussed mapmaking, and generally summarized Greek geographic knowledge at the peak of Roman power. Ptolemy's *geographia* was the resource for geographers until the Renaissance.

While the Arab geographers wrote in Arabic, many were not Arabs, but from ethnic groups that had converted to Islam. The Arab geographers included historians, astronomers, government officials such as postmasters, intelligence officers, travelers, as well as geographers. They were stimulated to study geography by the vast reaches of the Islamic world, the duty of the hajj, political control, and the great volume of commerce carried on caravans and in ships.

### IBN KHURRADADHEBEH

The first of the Arab geographers whose work is still extant was a Persian, Ibn Khurradadhebeh (circa 800s). Writing in Arabic, he was in charge of a postal system and an intelligence service. His geographical descriptions of the Islamic world and beyond were extensive. Other Arab geographers of the time were Ibn al-Faqih (d. 903) and Ibn Rusteh (d. 910), who also wrote descriptively of what could be known of the world and its peoples. Other geographers wrote in the 900s, including Mas'udi (d. 956). He described people like the Slavs, Lombards, and others from travelers' reports. He apparently used the work of al-Hakam, the emir of Cordova.

The Galkhi geography school included a number of notable Arab geographers. Among these were Ibn Hawqal and Abu Ishaq al-Istakhri. They divided the world of Islam (Dar al-Islam) into 20 categories. The world outside they put into the "house of war" (Dar al-Harab), as a separate category. They used both the older geographic knowledge and materials from the

Much of Arab geography stemmed from the need to locate the holy site of Mecca (above) from any direction.

Koran and the hadiths. Other schools, such as the Ikhwan al-Safa and the Ishraqi, described the world in zones and found symbolic meanings in "sacred geography" when concerned with holy cities like Jerusalem and Mecca.

Al-Muqaddasi (d. 1000) wrote a compendium of the physical and human geography of the known world. He based his geography on his own observations and those of dependable witnesses. Much of the information in the work of Ibn al-Faqih was cited by Al-Yaqut (d. 1229), who composed a geographical dictionary. Both were relying in part on the report of Harun ibn Yahya, who had been a prisoner in Rome around 886. In the late 900s, Aby Rayhan al-Biruni (973–1048) (born in Khwarazm, near the Aral Sea) wrote a number of short scientific works. His *Cartography*, showing map projections, is still extant.

The *Reconquista* and the Crusades brought increased contacts with the non-Muslim world, stimulating geographers such as Zuhri to write about Europeans. Others, such as the Persian Zakariya ibn Muhammad al-Qazvini (d.1283), used the work of earlier geographers like Ibn Ya'qub.

### AL-IDRIS

The greatest of the Arab geographers was Al-Idris (1100–1165). Abu 'Abd Allah Muhammad al-Idrisi is

often called ash-Sharif al-Idrisi. He was probably the greatest of all the medieval Arab geographers. Al-Idris was born at Sabtah, (Cueta) in North Africa in 1100. He studied at Cordoba, lived at Marrakesh for a while, and then traveled in North Africa during his youth. He may also have traveled some in Europe as well.

About the year 1145, al-Idris entered the service of Roger II of Sicily. Roger II was a Norman Christian king; however, al-Idris remained a Muslim. He continued at the Roger court as the royal geographer for the remainder of his life. It is likely that al-Idris stayed in Sicily to escape persecution. He was a Hummudid descendant and therefore a political threat as a legitimate claimant to the caliphate. Some Western scholars believe that al-Idrisi may have been seen as a renegade by other Muslims, because Muslim biographers wrote little about him after he joined Roger's court.

Al-Idris was a scientist, a geographer, and a map-maker. He wrote three major geographical works. One of them is the greatest of all medieval geographical treatises. In addition, he is believed to have written literary and medical volumes. During al-Idrisi's career in Sicily, he completed three major geographical works. Perhaps the most amazing was a silver planisphere on which was depicted a map of the world. The silver planisphere has been lost, but his maps and book have survived.

The second major work Al-Idris created was a world map. It consisted of 70 sections. The sections were formed by dividing the Earth north of the equator into seven climactic zones of equal width. Then each of the climactic zones was subdivided into ten equal parts by lines of longitude.

Al-Idris wrote a geographical text intended as a key to the planisphere. This was his great *al-mushtaq fi ikhtiraq al-afaq* (*The Pleasure Excursion of One Who Is Eager to Traverse the Regions of the World*) and which also is known as *Kitab Rujar* or *al-Kitab ar Rujari* (*The Book of Roger*).

The *Kitab Rujar* was a blend of empirical and rational methods. Like the Scholastics, he used materials from earlier Arabic and Greek geographical works. But this was combined with empirical information obtained through eyewitness reports. To get firsthand observation, al-Idris sent a group of people with training in geography and skill in drawing to a number of countries to record their observations.

Other geographical works are attributed to al-Idrisi, including one (now lost) written for William I (William the Bad), Roger's son and successor who reigned from 1154 to 1166, as well as several critical

revisions and abridgments. Al-Idrisi's scientific interests embraced medical matters as well geography. His *Kitab al-adwiya al-mufradad* (*Book of Simple Drugs*) lists the names of many drugs in as many as 12 languages, thereby giving a geopharmacology. He died in 1165 or 1166, but whether in Sicily or in his birthplace, Sabtah, is undetermined.

Geographers who came after Al-Idris were Ibn 'Abd al-Mun'im and Ibn Sa'id al (1210–74). The latter wrote *World Geography* in Spain, where he lived.

Ibn Battuta (d. 1377) was a devoted traveler who described vast areas of the Islamic world and Southeast Asia. Other travelers recorded the physical, human, and natural geography of the Islamic world as well as the routes of trade and travel. Among the historical contributors was Ibn Khaldun (1332–1404), who wrote the famous *Al-Muqaddimah*. It is an important book in the development of accurate history, and the opening chapters are an extensive geographical description of the peoples of the world.

Other geographers were concerned with specific aspects of geography. Qutb al-Din wrote a treatise on geometry and is included in the Maraghah school. He worked with the problem of classified knowledge. He organized such knowledge as philosophical (*al-hikmi*) and nonphilosophical (*ghayr al-hikmi*). Geography was in the latter category as nonreligious and non-philosophical (*ghayr al-diniy*).

A significant problem for Arab geographers was to find the direction of Mecca in order to face toward it. The direction is marked in a mosque by a qibla. To properly position it was a problem of mathematical geography that had to be solved. Often geometry merged with astronomy. Various methods were developed, but by the 10th century, tables had been developed that would locate the qibla as a function of geographic longitude and latitude. Others, like al-Biruni, working in India and elsewhere, attempted calculations on the size of the Earth.

The rise of the Ottoman Empire and other centers of Islam in the East shifted geographic writing into Turkish and Persian regions after the mid-1400s.

## Arabian Sea

THE ARABIAN SEA covers approximately 1,491,000 square mi (3,862,000 square km) and is located between the Arabian and Indian peninsulas in the northwestern area of the INDIAN OCEAN, bounded by INDIA, PAKISTAN, IRAN, OMAN, YEMEN, and the HORN OF AFRICA. The Arabian Sea has been the historic trade route from Occident to Orient since the dawn of commerce between the cradles of civilization. Dhows (sailing vessels) full of spices and slaves have given way to petroleum tankers and container ships, yet the trade continues unabated.

As early as the 8th century and onward, Arabian and Persian mariners learned to navigate this area by using prevailing winds and the surface currents generated by the summer and winter monsoons. For half the year (April–October), the winds in this region are from the southwest, reversing in the other half of the year. This monsoon (season) weather pattern dominates the region on land and sea, setting the pace of commercial activities and much of life.

Commercial fishing is a major activity in the Arabian Sea with the leading species fished being sardines, prawns, and mackerel. India accounts for 23.6 percent of its annual haul mostly from waters 6 to 9 mi (10 to 15 km) from the coast. Fishing stocks are being depleted because of a combination of overfishing and pollution along the Indian coast. Some 65 percent of all fish taken from the Arabian Sea continues to be from local fishermen in traditional boats as their single means of livelihood.

The overexploitation of fish stocks is mostly due to large fishing vessels operating illegally near the coast. The growth of regional populations, particularly India, will add pressure on the already challenged marine resources. This population increase and industrial devel-

opment create major pollution problems. Industrial effluents contain heavy metals and chemical wastes. Pesticides and organic wastes flow untreated into the coastal waters from cities and agricultural land. Oil pollution from accidents and ballast dumping is on the increase. The nations that share the management and use of the Arabian Sea have no comprehensive plan for conservation and management of the resources or uses of this critical area of ocean.

Primary branches of the Arabian Sea are the Gulf of Oman, which joins it to the Persian Gulf via the Strait of Hormuz and the Gulf of Aden, which joins it with the Red Sea via the BAB EL MANDEB. There are no islands in the middle of the Arabian Sea, where depths average in excess of 9,800 ft (3,000 m). Deep water reaches close to the bordering lands except in the northeast, off Pakistan and India. The deepest known point in the Arabian Sea is at Wheatley Deep, where depths are more than 19,000 ft (5,800 m). The principal waterway draining directly into the Arabian Sea is the INDUS RIVER. Coastal islands exist around the Arabian Sea and have proven significant for political and military purposes.

The sea is of geostrategic interest as it is the transit route for a major portion of the world's oil supply. In addition, the commerce flowing by ship from Asia to Europe also sails this sea.

## Aral Sea

THE ARAL SEA (Aral'skoye More) is one of the world's largest lakes or inland seas. It is located to the east of the CASPIAN SEA in the Central Asian republics of Kazakhstan and Uzbekistan. The region is arid, with the Karakum Desert lying to the west of the Aral Sea and the Kyzylkum Desert to the east. The sea is shallow with no outlet; the water level is determined by the balance between loss from evaporation, input from rivers, groundwater, and precipitation. Its main source of water is two rivers: the Syr Darya (the ancient River

Jaxartes) and the AMU DARYA (the ancient River Oxus), which rise in the foothills of the northern HIMALAYAN mountains.

During the last 3 million years, the lake has periodically flooded and experienced episodes of desiccation as the Earth has cooled and warmed. Recent changes are, however, the result of human activity, and the sea now has a negative water balance; that is, there is a net loss of water annually. This is mainly because the Amu Darya and Syr Darya are subject to considerable water extraction for irrigation. Consequently, the Aral Sea has shrunk in size, especially in the last 70 years as cotton production in Central Asia has intensified. Even in the last 40 years, the area of the Aral Sea has decreased by about 50 percent and its level has dropped by more than 56 ft (17 m). Almost 19.8 million acres (8 million hectares) of land in the region are now under irrigation, compared with only 7.4 million acres (2.9 million hectares) in 1900 and 12.4 million acres (5 million hectares) in 1960. Moreover, much irrigation is inefficient as water loss from the canal network is high through exposure of a large surface area of water that encourages evaporation. The Aral Sea is no longer one water body; its volume has decreased by two-thirds and since 2001 there have been three water bodies. The shoreline has decreased by 300 mi (480 km), isolating settlements from the water's edge in salt desert.

Water quality has also altered as salinity and mineral content have increased, and wind-blown sediment is a problem. Fish and wildlife losses have ensued and no commercial fishing is possible; vegetation cover has diminished as fewer species can tolerate the harsh environment. Livelihoods based on fishing and hunting have disappeared.

Human health problems have also developed, partly because of poor water quality attributed to contamination with agricultural chemicals. Average life expectancy is only about 40 years, the rate of infant mortality is three to eight times higher than that in the United States, and rates of miscarriage are high, as are incidences of viral hepatitis and tuberculosis. Inevitably, there is rapid depopulation because of these adverse conditions. Since the demise of the Soviet Union, cotton production has declined but without much difference in water extraction. The outlook is not encouraging. The exploitation of oil and gas reserves in the region may exacerbate an already acute environmental situation.

## Arctic Circle

LOCATED AT 66.5 degrees north latitude or 23.5 degrees southward of the North Pole, the Arctic Circle forms an imaginary line marking the northernmost location where the sun can be seen during the northern hemisphere's winter solstice (December 21). On June 22 and again on December 21, the circle of illumination (formed by the sun's rays striking the Earth) extends from the edge of the Arctic Circle in the north to the ANTARCTIC CIRCLE in the south.

On December 21, the sun is directly overhead at the TROPIC OF CAPRICORN (23.5 degrees south latitude) and the area within the Arctic Circle experiences 24 hours of darkness. On June 22, the sun is directly overhead at the TROPIC OF CANCER (23.5 degrees north latitude) and the area within the Arctic Circle experiences 24 hours of sunlight. On this day, the sun reaches its zenith (highest point) of 47 degrees above the horizon at noon and its nadir (lowest point) at midnight. Long periods of continuous sunlight during summer months have led to the area within the Arctic Circle being called "Land of the Midnight Sun."

The name *Arctic* comes from the Greek *arktos* meaning "bear," in reference to the position below the Great Bear constellation (Ursa Major). Located within the Arctic Circle are the ARCTIC OCEAN, the northern portion of GREENLAND, Baffin Island and the far northern parts of EUROPE, RUSSIA, ALASKA, and CANADA.

## Arctic National Wildlife Refuge

LOCATED IN northeastern ALASKA and managed by the U.S. Fish and Wildlife Service, the Arctic National

Wildlife Refuge (ANWR) encompasses the largest diversity of wildlife of any protected area in the circumpolar north, earning it the nickname “the American Serengeti.” Efforts to preserve the refuge began in 1960 with the establishment of the Arctic National Wildlife Range.

Following passage of the Alaskan Lands Act in 1980, the area was renamed the Arctic National Wildlife Refuge and its size expanded to 20 million acres (8 million hectares), approximately the size of SOUTH CAROLINA. Included within the refuge are 8 million acres (3 million hectares) of wilderness land.

The ANWR is bounded to the east by CANADA and to the north by the Beaufort Sea. At its seaward margin is the flat and treeless Arctic coastal plain, extending inland for 40 mi (64 km). To the south of the coastal plains is the Brooks Range, an east-west band of mountains with several 9,000-ft (2,750-m) peaks. The rugged glacial topography of the range is interspersed with ice fields and wide, steep-sided valleys. An active layer of permafrost, or permanently frozen soil, is found in most areas of the refuge. Permafrost extends downward to an average of 1,000 ft (300 m). Some permafrost areas are underlain with patterned ground formed by polygons measuring 30 to 200 ft (9 to 61 m) in diameter. The shape of polygons is influenced by spring meltwater seeping into surface cracks and freezing.

The climate of the coastal plain is classified as Arctic or sub-Arctic with cool, cloudy summers. The average July temperature is 41 degrees F (5 degrees C) and maximum temperatures rarely exceed 86 degrees F (30 degrees C). Winters are extremely cold, with February averaging -4 degrees F (-20 degrees C). High surface winds can result in windchill factors well below ambient temperatures. The Arctic plain receives an average of less than 10 in (25 cm) of precipitation. Two major biomes dominate the refuge: a northern boreal forest lying on the southern slope of the Brooks Range and Arctic tundra on the north slope. The ANWR has wildlife species common to the Arctic and sub-Arctic. More than 36 species of fish and nine marine mammals are represented in the refuge. Open range provides unconfined areas for large herds of porcupine caribou that migrate 800 mi (1,280 km) in May and June to ancestral calving areas on the coastal plain. In early July, they return to wintering areas to the south of the Brooks Range. Dall sheep can be found on mountain-sides and musk oxen near water sources on coastal plains. Polar bears move onshore during the winter and return to sea ice in the spring months to hunt seals.

Other ANWR mammals include lynx, voles, lemmings, and wolves. Proposals for petroleum drilling within the coastal plain have created controversy with regard to impacts on caribou and other wildlife in this Arctic region.

Bird nesting takes place between April and July. Represented within the refuge are the golden eagle, peregrine falcon, sandpiper, and plover. Migratory ducks and shorebirds begin collecting in lakes and lagoons in July to prepare for their migration to wintering areas in South America, Africa, Asia and the lower 48 U.S. states. Ptarmigan, dippers, and gyrfalcons are among the few species that remain in the refuge during the long Arctic winter.

OKLAHOMA STATE UNIVERSITY

## Arctic Ocean

THE ARCTIC is the smallest and shallowest of the Earth’s five oceans, occupying 4 percent of the world’s ocean space and surrounding the North Pole, the northernmost locale on the planet. The waters of the Arctic are fairly equidistant around the area, making the North Pole the approximate center of the ocean.

The majority of the Arctic Ocean is found north of the ARCTIC CIRCLE, which is one of the five circles of latitude marked on maps. Everything north of this line is considered the Arctic region; this area is mostly water, but the northernmost parts of ALASKA, CANADA, RUSSIA, NORWAY, and a significant portion of GREENLAND are within its borders. Therefore, most—but not all—of the Arctic Circle is ocean; and most—but not all—of the Arctic Ocean is north of the Arctic Circle.

Greek explorers of the late 300s B.C.E. discovered this ocean, with Pytheas reporting frozen waters located six days north of Britain. Ancient Greeks named these waters after the Arktos constellation found in extreme northern skies, a cluster of stars now known as Ursa Major or Great Bear.

The average depth is 3,407 ft (1,038 m) and its deepest point north of Svalbard, Norway, is 17,881 ft (5,450 m). Although some of the ocean is not deep at

all, the lowest point, Fram Basin, is -15,305 (-4,665 m) below sea level.

The lowest surface temperatures of the Arctic Ocean occur in February at -28 degrees F (-33 degrees C) and the highest in July at 29 degrees F (-2 degrees C); frozen precipitation averages 10 in (25 cm) annually and rarely melts. Because of constant cold, the central surface of the Arctic Ocean is covered with ice 10 ft (3 m) thick, and some ice can triple that thickness. During summer months, free-flowing water surrounds the ice; during the winter, ice thickness doubles and even extends to land adjacent to the ocean. Around June 22, the sun can still be seen on the horizon at midnight. This gives the region its nickname: Land of the Midnight Sun.

The Arctic connects with the ATLANTIC OCEAN by Greenland, and the Bering Strait merges the Arctic with the Pacific. The PACIFIC OCEAN is more than 13 times the size of the Arctic, but even the world's smallest ocean is 5,440,000 square mi (14 million square km), with a coastline of 28,203 mi (45,389 km), making the Arctic nearly 1.5 times the size of the UNITED STATES. Two significant waterways also connect to the ocean: the Northwest Passage, which flows into the United States and Canada; and the Northern Sea Route, which provides water to Norway and Russia.

The Arctic contains five continental shelves, which are areas of shallow, submerged land located along the edge of a coastline. When a continental shelf ends, there is generally a steep slope that descends into the largest portion of the ocean floor. One of these, the 900-mi (1,448-km) Siberian Shelf, is the largest continental shelf in the world; approximately 50 percent of the Arctic Ocean's floor consists of this geological feature. An underwater ocean ridge divides the Arctic into two basins.

Much of this ocean contains icebergs, frozen waters broken off from glaciers formed on the land. Some, especially those that form on Ellesmere Island and then break off (calve) into the Chukchi Sea, are large enough to be considered ice islands and last for several years. Once the icebergs hit the relatively warmer waters of the northern Atlantic, however, they melt fairly quickly. Few icebergs hit the Pacific, blocked from proceeding by the Bering Strait.

Fish, seals, walruses, and whales reside in these waters, and petroleum and natural gas is pumped out. The Arctic is also home to the only ocean bear on the planet. Because of the extreme cold and low sunlight in this region, this ocean is slow to adapt to or recover from environmental change; scientists are watching the

thinning of its polar ice and debating the connection between global warming and the shrinkage.

This region also provides scientists with information about pollution. Since it generates little of its own contaminants, the increase of pollutants found in the area help measure the world's increasing water and airborne toxicity.

## Argentina

**Map Page** 1141 **Area** 1,068,302 square mi (2,766,890 square km) **Capital** Buenos Aires **Population** 39,144,753 **Highest Point** 22,834 ft (6,960 m) **Lowest Point** -344 ft (-105 m) **GDP per capita** \$11,200 **Primary Natural Resources** iron ore, petroleum, uranium.

ARGENTINA IS A COUNTRY located in southern South America, the second-largest country on the continent. Argentina shares a long border with CHILE to the west. The two countries have disputed territory around the Beagle Channel in Tierra del Fuego. Argentina also borders on URUGUAY, PARAGUAY, BRAZIL, and BOLIVIA.

The country possesses a nearly 3,100-mi- (5,000-km-) long coastline on the ATLANTIC OCEAN. Argentine claims over the Islas Malvinas, or FALKLAND ISLANDS, has led to a dispute with Great Britain, which also claims the islands. The two countries fought a war over the Malvinas/Falklands in 1982, when the Argentina military invaded the islands. After a short but costly conflict, the British forcibly retook control of the islands.

Argentina can be divided into four main geographic regions: the ANDES, the North, the Pampas, and Patagonia.

The Andes Mountains form the “backbone” of Argentina along the western border with Chile. In the northern Andes, peaks average between 11,000 and 13,000 ft (3,353 and 3,962 m), although some can reach as high as 19,000 ft (5,791 m). There are a number of valleys in the north, including the broad quebradas that historically provided access to the Atlantic. There has been some mining in the northern Argentine Andes, including lead, zinc, copper, silver, and beryllium. As the Andes make their way south, the range narrows and the peaks get higher. Some of the highest mountains in the world can be found in the Central Argentine Andes. Among these high peaks is ACONCAGUA MOUNTAIN, the highest mountain in the Western Hemisphere at 22,834 ft.

### NORTHERN ARGENTINA

The northern part of the country can be divided into two parts: the Chaco region and the so-called Mesopotamia area. The Chaco is a large alluvial plain that stretches over territory in Argentina, Paraguay, Brazil, and Bolivia. The soil is made up of deposits that wash down from the Andes Mountains. The Chaco region is subject to major flooding during the summer rainy season. Much of the Chaco consists of woodlands of deciduous scrub trees that often grow densely packed together. There are also areas of grassy savannahs.

A subtropical climate and some of the highest temperatures in Latin America lead to rapid evaporation, which makes agriculture difficult without irrigation. These difficult physical conditions limited the agriculture practiced by the native inhabitants. Historically, the economy of the Chaco region depended on the *quebracho* forests, which provided a source of tannin used for the early Argentina leather industry. Many settlers moved to the region in the 19th century to exploit these forests after the defeat of the native peoples in the 1880s. In the 1930s, more settlers were attracted to the Chaco by cotton, which could withstand the sometimes long drought period in the region.

The Mesopotamia region, so named because of its location between the Paraná and Uruguay Rivers, includes the western Paraná plateau and a large lowland. Iguacu Falls is located in the region along the border with Brazil and Paraguay. Spanish settlers came to the region starting in the sixteenth century.

In the 17th century, Jesuit missionaries arrived in the area, giving the region the name of Misiones. Misiones is the center of production for yerba mate, used to make a tealike beverage. The Mesopotamia region

also possesses some excellent grazing land for cattle and sheep.

The plains area known as the Pampas is the heartland of Argentina. Historically, it has been the demographic, economic, political, and cultural center of the country. During the Spanish colonial period, the Pampas were an area of open grasslands with wild herds of horses and cattle derived from the animals that European settlers brought. The region's fertile soil has made agriculture easy and profitable. By the 19th century, ranching and grain farming dominated the Pampas. Wheat has been the key crop of the Pampas, although corn, barley, and flax have also been successfully grown. Traditionally, the Pampas was divided into large estates known in Argentina as *estancias*. The Pampas accounts for about 8 percent of the country's agricultural production.

Some 70 percent of the Argentine population resides in the Pampas region. Buenos Aires, the country's largest city and Argentina's capital, is located in there. Buenos Aires has long been the country's commercial and manufacturing center. It serves as the main port along the Río de la Plata. In the 19th century, the advent of the railroad connected the city with the surrounding Pampas, bringing agricultural products to the port quickly and cheaply. Other major cities in the region include Rosario, Córdoba, and Mar del Plata. In addition to being the demographic center of the country, the Pampas region is home to more than 80 percent of Argentina's industry.

The southern lowlands of South America south of the Colorado River are known as Patagonia. The region consists mostly of cool, arid, and windswept STEPPES. The climate of Patagonia is generally mild. Inland and to the south, there are moister, more productive grasslands that can be used for grazing. However, much of the region is desert, with rainfall under ten inches annually. The lack of rainfall is due to the barrier created by the Andes Mountains and the Falkland Current.

Patagonia was unsettled by Europeans until the second half of the 19th century. In the 1860s, immigrants from Wales settled along the Chubut River. After the “Conquest of the Desert” in the 1880s, when the Argentine government militarily subdued the Native Americans in Patagonia, Argentine and European settlers moved into the region. The wave of migrants led to the establishment of large sheep ranches in Patagonia. Other economic activities included fruit orchards, vineyards, dairy farms, and coal mining. In the early 20th century, petroleum became an important re-

source in the region and led to the creation of Comodoro Rivadavia, which serves as the center of Argentina oil production.

The region is sparsely populated. Patagonia accounts for about one-fourth of the country's land but possesses only about 1 percent of the population. The most developed part of Patagonia is in the north, close to the Pampas. The principal city in the region is Neuquén, located in the upper Río Negro Valley. The southern part of Patagonia is much less developed. Ushuaia is the southernmost town in the world.

## Arizona

A PLACE OF indisputable geographical interest in the U.S. Southwest, of which the GRAND CANYON of the Colorado River is but the leading example, Arizona currently exemplifies a trend toward urbanization in western states. While much of Arizona's land area of 113,635 square mi (294,315 square km) remains undeveloped, Arizona's capital and largest city, Phoenix, alone accounts for more than a quarter of the state's total population of 5,130,632 (2000 U. S. census).

Arizona was the last of the contiguous UNITED STATES to be granted statehood, in 1912. Statehood followed a long territorial history, beginning with the combination of a portion of the land area ceded to the United States by MEXICO in 1848 and the Gadsden Purchase of 1853 in the Territory of New Mexico. Arizona was organized as a separate territory in 1863. The state is bounded by UTAH, NEW MEXICO, CALIFORNIA, and NEVADA, and by Mexico to the south. The propriety of including the extreme northwestern land area, known as the Arizona strip, has long been a matter of dispute with adjoining Utah, due to its relative inaccessibility from greater Arizona across the Colorado River.

Three physiographic provinces divide the state into a continuity of diverse regions. To the north, the Colorado Plateau Province rises to a maximum altitude at

Humphreys Peak (12,633 ft or 3,851 m). Composed primarily of Paleozoic sedimentary strata, the plateau is joined from several interlocking uplifted blocks, terminating on the southern boundary at the Mogollon Rim. The Grand Canyon cuts through the southwestern corner of the plateau, exposing a vast geological column that terminates in pre-Cambrian gneiss at the level of the Colorado River. Volcanic activity, seen in a field of cinder cones to the south of the canyon, has been recent; Sunset Crater, a cinder cone northeast of Flagstaff, is less than 1,000 years old. South of the Mogollon Rim are the Central Highlands, a province that is also termed the Transition Zone because the province shares characteristics of the Colorado Plateau and of the Basin and Range to the south and west. The southern and western extents of Arizona are the Basin and Range Province, a region of mountain ranges composed of volcanic rocks, separated by deep grabbens choked with alluvium.

Most of the Basin and Range Province is arid and is classified as desert. The SONORAN DESERT, which dominates the province and continues into Mexico and California, has two seasons of rainfall—in summer and winter—in its central portion, known as the Arizona Upland. This biannual rainfall provides up to ten inches of precipitation annually, making the Arizona Upland the most lush of American desert landscapes. Its unique plants include the saguaro, a columnar cactus that can reach 50 ft (15 m) in height. High temperatures in summer easily reach into the 110s degrees F (40s degrees C) in portions of the region. Because of its altitude, the Colorado Plateau enjoys a more moderate climate, although it too is arid. In a swath that crosses the Grand Canyon and extends along the Mogollon Rim above 6,000 ft (1,800 m), ponderosa pine form the largest continuous forest of this species in the United States. Winter snowfall is common on the plateau but can occur throughout the state, infrequently in the mountains surrounding Tucson in the south.

## HUMAN GEOGRAPHY

Humans have had a presence within the state's boundaries for more than 10,000 years, and relatively arid conditions have preserved "soft" artifacts from much of that range in time. Evidence of permanent and semi-permanent settlements, dependent in part on agriculture, begins appearing in the archaeological record about 2000 B.C.E. From these roots, two great civilizations with urban centers, the Puebloan (often called Anasazi) on the Colorado Plateau and the Hohokam in

the Sonoran Desert, arose to exploit the region's resources. Both of these civilizations dispersed from urban centers around 1400, following periods of civil strife, decreasing annual rainfall, and the expansion of the Dine (Navajo) and Apache from the north. Descendants of Puebloans include the Hopi; the Hohokam left descendants among the Pima, Maricopa, and Tohono O'odham.

Although the Spanish perfunctorily explored the region after the conquest of Mexico, the inhospitable landscape combined with resistance from native peoples stopped Spanish colonization at Tucson. Further incursions of Euro-Americans did not occur until Anglo-Americans began to exploit the region's mineral resources, which included silver and copper; marginal grazing lands; and timber in the 19th century. Agriculture had a lesser place in the region's territorial economy until after 1911, when the Roosevelt Dam on the Salt River opened the desert around and south of Phoenix to dependable irrigation for cotton and other crops. Improvements in transportation and air-conditioning technology, following World War II, drove a real estate boom and led to a rise in Arizona's population and a diverse and technologically modern economy.

UNIVERSITY OF CALIFORNIA, SAN DIEGO

## Arkansas

**ITS NAME DERIVED** from a French-adapted Native American term meaning "downstream people," Arkansas is the 27th largest state at 53,104 square mi (137,539 square km). The state's shape is almost like a box, as its north-south extent is 240 mi (386 km) and the east-west extent is 275 mi (443 km).

Located in the mid-Southwest UNITED STATES, landlocked Arkansas is bordered by six other states: MIS-

SOURI, TENNESSEE, MISSISSIPPI, LOUISIANA, TEXAS, and OKLAHOMA.

The longest river in Arkansas is the White River, a tributary of the MISSISSIPPI, running 1,485 mi (2,388 km) to the southeast. The largest lake in the state is an artificial one, Lake Ouachita (60 square mi or 155 square km), located in the middle west of the state. The largest natural lake in the state is Lake Chicot, which is an oxbow of the Mississippi in southeast Arkansas.

There are several distinct physical regions of Arkansas. In the northwest are the highlands of the heavily forested Ozark Plateau and Boston Mountains. South of this area is the Ouachita Mountain range, which includes the highest peak in Arkansas, Magazine Mountain, at 2,753 ft (839 m). The rest of the land in Arkansas is mainly lowlands of the Mississippi valley. This is where the most fertile soil of Arkansas is located. Nearly half of Arkansas is covered with forests. In the Mississippi plains, there are the hardwood forests, consisting of such trees as elm, oak, and ash, and the softwood forests are in the western area, consisting mainly of simply pine trees. Arkansas is also host to many flowering trees, such as the dogwood and the red haw. The state has a wide range of animal life, with fish such as perch and drum, birds such as geese, ducks, and turkey, reptiles like snakes, lizards, and turtles, and mammals such as deer, bobcats, and minks, all call Arkansas home.

The CLIMATE of Arkansas is moist and mild. There are warm/hot summers and winters are cool. The highland region is slightly cooler. Littler Rock, the capital, has average temperatures of 40 degrees F (4.4 degrees C) and 82 degrees F (27.7 degrees C) in January and July, respectively. The 49 in (124 cm) of annual precipitation comes mostly in the winter and spring. There is a slight difference between the north and the south of the state, where in the north, more specifically the Ouachita Mountains, rainfall averages 54 in (137 cm) a year. In Little Rock the average is 42 in (107 cm) a year. One of the great dangers in Arkansas is TORNADOES; the far north and southwest parts of the state are the most prone to them.

Arkansas was first explored in 1541 by Hernando de Soto for the Spanish, but it wasn't until 1673 that Jacques Marquette traveled the Mississippi to Arkansas and declared it to be French land. John Law, in 1717, attempted to set up the first settlement in the Mississippi valley, but it failed. In 1762, the French ceded the territory over to the Spanish, but then in 1800 reclaimed it, only to sell it three years later to the United States, in the famous LOUISIANA PURCHASE.

Three years after, that the District of Arkansas was created, and after a slow development, more than 30 years later Arkansas was admitted as the 25th state of the Union.

Arkansas is a landmark for civil rights history, as in 1957 and 1958, when the Supreme Court case of *Brown v. Board of Education* was challenged by the governor of Arkansas at the time, Orval Faubus. President Dwight Eisenhower called in troops to ensure that African Americans were integrated into Arkansas public schools.

GOLSON BOOKS, LTD.

## Armenia

**Map Page** 1121 **Area** 11,500 square mi (29,800 square km) **Population** 3,326,448 **Capital** Yerevan **Highest Point** 13,418 ft (4,090 m) **Lowest Point** 1,312 ft (400 m) **GDP per capita** \$3,900 **Primary Natural Resources** hydroelectric potential.

ARMENIA, LYING SOUTH of the towering CAUCASUS range and on the southwestern edge of Asia, is bounded to the north and east by the republics of GEORGIA and AZERBAIJAN, while landlocked to the southeast and west by IRAN and TURKEY.

There is a disputed exclave of Nagorno-Karabakh surrounded by Muslim Azerbaijan. Modern Armenia, a former republic of the Soviet Union, is a small portion of one of the world's oldest centers of civilization, which in the 1st century B.C.E. extended from the BLACK and MEDITERRANEAN seas to the CASPIAN SEA and central Iran. Armenians comprise more than 90 percent of the populations, with the rest being Kurds, Azerbaijanis, Russians, Ukrainians, and others. In 1995, Armenians established a republic, consisting of an elected presi-

dent, an appointed prime minister and cabinet, a 131-member national assembly, and a judiciary branch.

Mountains and elevated volcanic plateaus dominate much of the country, with STEPPE or mountain grasslands in the lower elevations. The land is subject to tectonic activity. On December 7, 1988, a strong earthquake in the northwest destroyed towns and killed about 25,000 people. Only 17 percent of the land is arable and irrigation from its rivers and Lake Sevan is used to help with the aridity of the landscape. Its climate is classified as highland continental, with cold winters and hot dry summers, making autumn the most pleasant season. Rainfall is as much as 32 in (81 cm) on mountain slopes, but it decreases into the plains. Altitudinal zonation of climate determines the variety of crops grown on the Lower Caucasus Mountains.

Under the old Soviet central planning, Armenia developed an industrial focus on machine tools, textiles, and other products, but the machinery is now outdated and privatization is only recently improving industry. More than 15 soil types occur in the country but the hilly, rocky nature of the land along with its aridity inhibits a return to small-scale agriculture. Therefore, Armenia is forced to import foodstuffs. Lamb is the staple meat; fruits, beans, chickpeas, eggplant, yogurt, tabbouleh, and other Middle Eastern dishes make up the rest of the diet.

The Muslim economic blockade of Christian Armenia has cut off most of its oil importation, although the Armenian exclave of Nagorno-Karabakh has vast untapped oil reserves. Hydroelectric power is provided from its rivers and it has been forced to reopen its antiquated nuclear power plant at Metasamor.

Geopolitically, Armenia's conflicted history sheds significant light on cultural development. Once this Indo-European people settled in the region at the beginning of the 6th century, their location on the SILK ROAD and a military corridor drew numerous conquerors and competitors for the land. Medes, Persians, Greeks, Romans, Byzantines, Mongols, Egyptian Mamluks, Ottoman Turks, and Russians all invaded the area. Armenia's conversion to Christianity in 300 ultimately brought them into conflict with Muslim neighbors.

In the early 20th century, emerging Turkish nationalism led to the deportation or killing of 600,000 to 2,000,000 Armenians. Expanding Soviet communism created a small republic, but the Soviet Union's collapse led to a struggle with Muslim Azerbaijan for control of Nagorno-Karabakh. Temporary success produced

a crippling blockade by the surrounding Muslim powers. The new government is trying to lift the land out of its economic and political woes.

## Aruba

A NETHERLANDS territory in the CARIBBEAN SEA and formerly the A in the ABC Islands, Aruba has come into its own in the past two decades, thanks in large part to aggressive advertisement campaigns on U.S. television. Already prosperous due to oil refineries established by the Dutch in the early 20th century, this advertising strategy aims to make tourism the number-one element in the Aruban economy, long before petroleum resources are used up.

Aruba has an area of 75 square mi (193 square km), and its capital city is Oranjestad. The highest point is Mount Jamanota at 617 ft (188 m) and lowest point is seal level. A population of 70,844 enjoys a gross domestic product per capita of \$28,000.

Aruba lies only 15.5 mi (25 km) off the north coast of VENEZUELA and a few miles west of the other Dutch islands of Curaçao and Bonaire. The islands became a Dutch colony in 1636 but retained a diverse population of local natives, Dutch, Spanish, Portuguese, and English traders, resulting in the curious language combining all of these elements known as Papiamentu. Aruba alone of the Caribbean islands has retained a significant portion of its pre-European population (Arawak), mainly because the islands are too arid to have been developed as commercial tobacco or sugar plantations in the 17th century.

Instead, the ABC Islands became a center of piracy, raiding the rich Spanish galleons as they left the South American ports for Europe and developing as the center of the Caribbean slave trade. Hit hard by the abolition of slavery by the Dutch in 1863, the islands first reinvented themselves as center for the South American

gold rush of the 19th century, then as primary refiners of oil from the Maracaibo oil fields in Venezuela in the early 20th century. The first refinery on Aruba was built in 1920s, at the time the largest of its kind in the world.

Unlike the more tropical islands of the eastern Caribbean, the islands off the coast of South America have a more arid climate, where cacti and aloe vera thrive. The islands are outside the hurricane belt and are sunny and dry (less than 25 in or 64 cm of rain per year), which is a draw for tourists, but also creates the problem of finding freshwater for the large amount of visitors arriving each year, mostly from the UNITED STATES and Venezuela. Large water collection facilities have been set up on Aruba to convert seawater to drinking water, and in the process, this has created a subindustry of salt production. Tourism is an appealing alternative to dependence on Venezuelan oil, which began to diminish after Venezuela opened its own refineries in the 1980s.

Resenting the dominance of its larger neighbor, Curaçao, Aruba seceded from the Netherlands Antilles in 1986 and became a separate, autonomous member of the Kingdom of the Netherlands. Movement toward full political independence was halted at Aruba's request in 1990.

SMITHSONIAN INSTITUTION

## Ascension Island

ASCENSION ISLAND IS an overseas territory that forms part of a single territorial grouping (with ST. HELENA and Tristan da Cunha) under the sovereignty of the British crown. Ascension is a small island, 35 square mi (90 square km), of volcanic origin between Africa and South America, just south of the equator. The capital is Georgetown.

Ascension is a rocky peak with 44 distinct craters, all dormant, with its base just west of the mid-Atlantic

ridge. Much of the island is covered by basalt lava flows and cinder cones. The last major volcanic eruption took place about 600 years ago. The highest point (Green Mountain), at some 2,817 ft (858 m), is covered with lush vegetation, which with each rainy season is increasingly spreading throughout the island. The climate on Ascension Island is subtropical, with temperatures at sea level ranging from 68 to 88 degrees F (20 to 31 degrees C) and about 10 degrees F (6 degrees C) less on Green Mountain. Showers occur throughout the year, with slightly heavier rains in the January to April period.

Ascension was discovered by the Portuguese in 1501, claimed by them on Ascension Day, 1503, and settled by the British dating from the 19th century. The island's economic importance (cattle, sheep, fish, turtles, etc.) was always superseded by the military role with its strategic position within the South Atlantic. The British first occupied the island as a strategic geographical base for their global naval interests in the emerging British Empire. Ascension received greater importance as a cable and later wireless station in the late 19th century. During World War II, the Americans used this British island to control naval activities in the South Atlantic. Ascension maintained this strategic military role during the Cold War and also assumed some new functions for the U.S. space program under the National Aeronautics and Space Administration (NASA).

The British renewed their interest in Ascension Island during, and ever since, the Falklands War in 1982. Its position halfway between Britain and the Falkland Islands made Ascension Island the much needed logistic center for the British military operations in the Southern Hemisphere. Most of the inhabitants (about 1,000 people) originate from St. Helena, 750 mi (1,207 km) to the southeast, but there is quite a number of British and U.S. military personnel as well. Ascension was politically dependent on St. Helena but has become more self-governed within the last decades. Fishing will probably remain the most important economic factor of the island, as tourism was always hampered by the remoteness of the territory and the large military presence.

**BIBLIOGRAPHY.** Duff Hart Davis, *Ascension: The Story of a South Atlantic Island* (Constable, 1972); Sue Steiner, *St. Helena, Ascension, Tristan da Cunha* (Globe Pequot, 2002).

OLIVER BENJAMIN HEMMERLE  
CHEMNITZ UNIVERSITY, GERMANY

## Atlantic Ocean

THE NAME OF THE Atlantic Ocean is derived from the Greek god Atlas and means “Sea of Atlas.” Its area is approximately 41 million square mi (106 million square km) including its adjacent seas; volume is approximately 85 million cubic mi (354 million cubic km), including adjacent areas. The average depth of the ocean with adjacent seas is 10,932 ft (3,332 m). The greatest depth is in the North Atlantic at 28,232 ft (8,605 m) in the Milwaukee Deep of the Puerto Rico Trench just north of PUERTO RICO; in the South Atlantic, the greatest depth is 27,651 ft (8,428 m) at the South Sandwich Trench east of the Falkland Islands. The width of the Atlantic varies from 1,769 mi (2,848 km) between Brazil and Liberia to about 3,000 mi (4,830 km) between the United States and northern Africa.

The ocean has a coastline of 69,357 mi (111,866 km). Adjacent areas include the CARIBBEAN SEA, Gulf of Mexico, Gulf of St. Lawrence, Hudson Bay, Baffin Bay, MEDITERRANEAN SEA, BLACK SEA, North Sea, Baltic Sea, Barents Sea, Norwegian-Greenland Sea, and Weddell Sea.

The Atlantic Ocean is the second-largest of the Earth's oceans. Covering approximately 20 percent of globe's surface, the Atlantic is second only to the PACIFIC OCEAN in size. Because the continents bordering its waters in the north are offset to the west of those in the south, the Atlantic appears as an elongated north-south S-shaped channel. In the north, the Atlantic is bounded by North America on the west and Europe on the east, while in the south it is bounded by South America on the west and Africa on the east. It is also linked to the Pacific Ocean by the ARCTIC OCEAN in the north and by the Drake Passage in the south.

The dividing line between the Atlantic and the INDIAN OCEAN to the east has been arbitrarily set at the 20 degrees E meridian, while the dividing line with the Pacific Ocean on the west follows the line of shallowest depth between Cape Horn and the Antarctic Peninsula. In the north, the boundary between the North Atlantic and the Arctic Ocean lies along a system of submarine ridges that extend between Baffin Island, GREENLAND, and Scotland. There is also a boundary between the Atlantic's northern and southern zones, formed by the equatorial counter currents that circulate just north of the equator (8 degrees north latitude) in an area known as the Intertropical Convergence Zone (ITCZ).

The Atlantic Ocean appears to be the youngest of the world's oceans. It began to form during the Jurassic

period, about 150 million years ago, when a rift opened up in the supercontinent of Gondwanaland, resulting in the separation of South America and Africa. The separation continues today at the rate of several centimeters a year along the Mid-Atlantic Ridge, a great submarine mountain range that extends from ICELAND in the north to approximately 60 degrees south latitude, dividing the Atlantic into a series of somewhat equal basins (also known as ABYSSAL PLAINS). Roughly 930 mi (1500 km) wide, the ridge has a more rugged topography than any mountain range on land and ranges from about 0.6 to 2 mi (about 1 to 3 km) above the ocean bottom. The ridge is a continuous feature of the Atlantic floor with one exception, the Romanche Furrow near the equator where the crest of the ridge drops significantly (15,000 ft or 4,573m) below the surface, allowing deep waters to flow freely between the Atlantic's eastern and western basins. Other transverse ridges running between the continents and the Mid-Atlantic Ridge divide the ocean floor into numerous other sub-basins including the Guiana, North American, Cape Verde, and Canaries basins in the North Atlantic and the Angola, Cape, Argentina, and Brazil basins in the South Atlantic. The large Atlantic-Antarctic Basin lies between the southernmost extension of the Mid-Atlantic Ridge and the Antarctic continent.

Although all of its abyssal basins are deeper than 16,400 ft (5,000 m), with many beyond 19,680 ft (6,000 m), the average depth of the Atlantic Ocean is 2 mi (3,300 m), less than the mean depths of both the Pacific and Indian oceans. Unlike the other oceans, the Atlantic has a high percentage (13 percent) of shelf seas (areas where continental crust is covered by water), which is two to three times the percentage found in the other oceans.

The Atlantic has a relatively small number of islands in comparison to the Pacific, with the greatest concentration found in the Caribbean region. Most of the islands are structurally part of the continents. The major islands of the Atlantic include Svalbard, Greenland, Iceland, Great Britain, IRELAND, Fernando de Noronha, the AZORES, the Madeira Islands, the CANARY ISLANDS, the CAPE VERDE Islands, BERMUDA, the West Indies, ASCENSION, ST. HELENA, Tristan da Cunha, the FALKLAND ISLANDS, and the SOUTH GEORGIA Islands. NEWFOUNDLAND is the principal island on the North American shelf, the British Isles the major island group of the Eurafrikan shelf, the Falkland Islands the only major group on the South American shelf, and the South Sandwich Islands on the Antarctic shelf. The is-

lands of Puerto Rico, Hispaniola, JAMAICA, and CUBA (the Antilles) are part of an oceanic arc, while the Madeiras, Canaries, Cape Verde, and the Sao Tome and Principe group are the peaks of submarine ridges. The Azores, Saint Paul's Rocks, Ascension, and the Tristan da Cunha group are peaks of the Mid-Atlantic Ridge system, while the large island of Iceland is a volcanic hotspot at the northern end of the Mid-Atlantic Ridge. Bermuda rises from the floor of the North American Basin, and St. Helena from the Angola Basin.

The Atlantic consists of four major water masses. The North and South Atlantic central waters constitute the surface waters. Sub-Antarctic intermediate waters extend to depths of 3,300 ft (1,000 m), while the North Atlantic deep waters reach depths of as much as 13,200 ft (4,000 m). The Antarctic bottom waters are found at depths greater than 13,200 ft (4,000 m). Waters in the North Atlantic have a clockwise circulation (due to the Coriolis force), while those in the South Atlantic circulate counterclockwise. In addition, the land area that drains into the Atlantic is four times that of either the Pacific or Indian oceans. The major river drainage basins affecting the Atlantic include waters from many of the principal rivers of the world, among them the ST. LAWRENCE, MISSISSIPPI, Orinoco, AMAZON, Paraná, CONGO, NIGER, and LOIRE, and the rivers emptying into the North, Baltic, and MEDITERRANEAN seas.

The circulatory system of the Atlantic's surface waters consists of two large gyres (or circular current systems), with one in the North Atlantic and the other in the South Atlantic. These gyres or current systems tend to be wind driven but are also influenced by the rotation of the Earth. The currents of the North Atlantic (the North Equatorial Current, the Canaries Current, and the GULF STREAM) flow in a clockwise direction from the equator to about 45 degrees north latitude, while those in the South Atlantic (the Brazil, Benguela, and South Equatorial currents) flow counterclockwise from near the equator to about 45 degrees south latitude. As you approach the polar zones, the currents are less completely defined, with one rotating counterclockwise in the Arctic regions of the North Atlantic and another in the South Atlantic rotating clockwise near Antarctica.

Surface salinity values are influenced by evaporation, precipitation, river inflow, and melting of sea ice. The salinity of the surface waters in the open Atlantic range from 33 to 37 parts per thousand, depending on latitude and season. Minimum salinity values are usually found at high latitudes and along coasts of continents where large river flows affect concentration.

Given the volume of water discharged by the Amazon River in northeastern South America, minimum salinity values for the Atlantic are found just north of the equator. The area with the highest salinity values occurs in a part of the Atlantic referred to as the SARGASSO SEA. The Sargasso is somewhat of an ocean desert, with very little rainfall. Given the regions latitude, rates of evapotranspiration (evaporation exceeding rainfall) are quite high leading to the high salinity values in the surface waters.

Surface water temperatures, which are influenced by latitude, current systems, and season, range from 28 degrees F to 84 degrees F (-2 degrees C to 29 degrees C). The most active circulation is found in the uppermost layer of warm water. Below this, circulation becomes increasingly sluggish as the temperature decreases. Surface temperatures range from 32 degrees F (0 degrees C) at the Arctic and Antarctic margins, to 81 degrees F (27 degrees C) at the equator. At depths below about 6,600 ft (2,000 m), temperatures of 36 degrees F (2 degrees C) are prevalent; and in bottom waters, those below 13,200 ft (4,000 m), temperatures of 30 degrees F (-1 degrees C) are common.

The ocean has also contributed significantly to the development and economy of the countries around it. Besides its major transatlantic transportation and communication routes, the Atlantic contains some of the world's most productive fisheries. The most productive of these include the Grand Banks off Newfoundland, the shelf area off Nova Scotia, Georges Bank off Cape Cod, the Bahama Banks, the waters around Iceland, the Irish Sea, the Dogger Bank near the North Sea, and the Falkland Banks. The major species of fish caught in these areas are cod, haddock, hake, herring, and mackerel.

There are also abundant petroleum deposits in the sedimentary rocks of the continental shelves. Large amounts of petroleum are currently being extracted in the North Sea and in the Caribbean Sea and Gulf of Mexico region, with lesser amounts coming from the Gulf of Guinea near the African coast. Actively mined mineral resources include titanium, zircon, and monazite (phosphates of the cerium metals), off the eastern coast of Florida, and tin and iron ore, off the equatorial coast of Africa.

## PORTS AND HARBORS

The Atlantic is currently served by a large number of ports and harbors, including major ports or harbors in Alexandria (EGYPT), Algiers (ALGERIA), Antwerp (BELGIUM), Barcelona (SPAIN), Buenos Aires (ARGENTINA),

Casablanca (MOROCCO), Colon (PANAMA), Copenhagen (DENMARK), Cork (Ireland), Dakar (SENEGAL), Gdansk (POLAND), Hamburg (GERMANY), Halifax, Nova Scotia (CANADA), Helsinki (FINLAND), Las Palmas (Canary Islands, Spain), Le Havre (FRANCE), Lisbon (PORTUGAL), Liverpool (UNITED KINGDOM [UK]), London (UK), Marseille (France), Montevideo (URUGUAY), Montreal (Canada), Naples (ITALY), New Orleans (UNITED STATES), New York (United States), Newport News (United States) Oran (Algeria), Oslo (NORWAY), Peiraeus (GREECE), Rio de Janeiro (BRAZIL), Rotterdam (NETHERLANDS), Saint Petersburg (RUSSIA), Southampton (UK), and Stockholm (SWEDEN). While these ports play active roles in the economies of the countries bordering the Atlantic, the PANAMA and Suez canals (as links to the Pacific and Indian oceans) greatly enhanced that value by shortening the distance to markets on the Pacific Rim or within the Indian Ocean.

The Atlantic is currently faced with a number of important environmental issues, including endangered marine species (manatees, seals, sea lions, turtles, and whales); drift net fishing; municipal sludge pollution from the eastern United States, southern Brazil, and eastern Argentina; oil pollution in the Caribbean Sea, Gulf of Mexico, Lake Maracaibo, Mediterranean Sea, and North Sea; and industrial waste and municipal sewage pollution in the Baltic Sea, North Sea, and Mediterranean Sea.

Natural hazards include icebergs, which are common in the Davis Strait, Denmark Strait, and the northwestern Atlantic Ocean, particularly between February and August. Occasionally, they have been spotted as far south as Bermuda and the Madeira Islands. Ships traveling in the extreme northern Atlantic from October to May are subject to heavy icing on their superstructure, and persistent fog can be a major hazard anytime between May and September. Hurricanes also pose a significant threat to the land areas along the Atlantic coast and tend to be most common between May and December.

## Atlas Mountains

THE ATLAS MOUNTAINS of northwest Africa are an elaborate assemblage of mountain ranges that trend from southern coastal MOROCCO and the CANARY ISLANDS, through ALGERIA into coastal TUNISIA. Extending more than 1,500 km (932 mi) and chiefly composed of sedimentary and igneous rocks that have been folded and faulted over the past 85 to 150 million years, the Atlas peaks are a part of the Tethyan Mountain network, an immense mountain group that extends roughly 6,700 mi (11,000 km) and includes the ALPS and Carpathians of Europe, and the CAUCASUS, ZAGROS, Pamir, and the HIMALAYAN mountains of Asia. Furthermore, earthquakes occur regularly along this complex chain, indicating that mountain-building is still taking place.

In Morocco, the Atlas Mountains (“Idrren Dnren” in Berber) consist of four chains: the High, Middle, Anti, and Rif ranges separated by fertile and productive plains. Although the Rif Mountains are traditionally considered not a part of the Atlas system, their uplift epoch, or orogeny, and general trend indicate that they are related. Likewise, although the Middle (Moyen) Atlas are considered a separate range, topographically they are a lower extension of the High (Haute) Atlas complex, where the great Jebel Toubkal rises tallest in the chain at 13,665 ft (4,165 m).

As the mountains bend into Algeria’s arid backcountry, the steep peaks flatten into distinctive plateaus. Here, the range has two particular spines: the northern, coastal Tell (or Maritime) Atlas chain and the southern, inland Saharan Atlas Mountains. As they head to the northeast, these ranges encircle the Chott Plateau before consolidating into a single range that follows the coast across Algeria into northern Tunisia.

The Atlas chain also plays an important role in modifying the climate throughout the region. Dividing the mild Atlantic and Mediterranean coasts from the SAHARA DESERT’s harsh environment, western and northern slopes receive greater amounts of rain and snow, sustaining numerous farms and orchards along

the headwaters of Morocco’s and Algeria’s ephemeral rivers and wadis (dry riverbeds except in the rainy season). The slopes to the east and south, however, commonly support xeric vegetation like grasses and shrubs and common arid land features like salt pans and dry lake beds influenced from the rains shadow of the mountains.

The Atlas Mountains are also rich in minerals and oil. Phosphate, and metal ores including lead, zinc, copper, silver, manganese are productive commodities, while important coal deposits and petroleum reserves are managed in Morocco, Algeria, and Tunisia. Into the 2000s, as tourism and recreation programs develop throughout the region, the Atlas Mountains are attracting thousands of travelers during the winter each year to ski and trek in the snow, and in the warmer months, tourists can backpack, tour, and hike all across the vast area. The highest peaks of the Atlas Mountains include Jebel Toubkal in the High Atlas Range; Jebel Siroua in the Anti-Atlas Range, 10,843 ft (3,305 m); Jebel Tidiquin in the Rif Mountains, 7,835 ft (2,448 m); Jebel Chelia in Saharan (Aures) Atlas, 7,638 ft (2,328 m).

## aurora borealis

NORTHERN LIGHTS, or the aurora borealis, are shimmering lights that shine above the Earth near the geomagnetic North Pole. The lights, often bright enough to read by, are usually green or red. The phenomenon is caused when a solar storm discharges high-energy particles that are channeled into a ring by the Earth’s magnetic field. The solar particles energize atoms in the thin ionosphere, which cause emissions of light.

The solar particles travel from the sun in a field called, at different stages, a plasma or solar wind. Because the solar wind and the magnetic field of the

Earth are constantly interacting, the northern lights may appear as an arc, a curtain, or an undulating sheet. When the electrons from the sun excite oxygen atoms, those atoms glow green. If they get extremely excited, red is the color produced. Blue and violet lights result from interaction with nitrogen radicals, a pink glow comes from neutral nitrogen, and excited hydrogen shows as blue and green. Each color glows at a particular altitude as well. Thus, the auroras can actually serve as a map of the composition of the ionosphere.

The aurora borealis usually glows from 50 to 100 mi (80 to 160 km) above the ground, but it can occur at lower altitudes and, on rare occasions, at ground level. Astronauts, the only persons who get to see the lights from above, have flown through auroras and report that even with eyes closed, they see flashes of light from the charged particles as those particles pass through their eyeballs.

The solar particles that react with Earth's atmosphere to form the lights circle the geomagnetic poles, so the aurora borealis is usually seen in places above a latitude of 30 degrees. The land areas that see most displays of northern lights include northern ALASKA, the Hudson Bay region, ICELAND, and northern Scandinavia. Clear nights in these areas are dark enough to view the lights from September to April. Since the lights are brightest following solar storms, several websites provide updated forecasts of such activity. Following earlier research, scientists in 1957 and 1958—the International Geophysical Year—mapped an oval band, about 310 mi (500 km) wide, that circles Earth's magnetic poles. Within this band, about 1,250 mi (2,000 km) from the pole, the aurora borealis can be seen on almost every dark night.

Areas as far south as the New England portion of the UNITED STATES may see an aurora borealis several times during the year, but sightings farther south are rare. Very large solar storms have resulted in lights being seen far south of the usual viewing range, but this happens only once per decade, on average. An aurora in 1859 was observed as far south as Honolulu, HAWAII.

Observations of the northern lights date back to the time of Aristotle, who described an aurora around 349 B.C.E. A Viking record titled Kongespeilet (King's Mirror), written circa 1250 C.E. states that the light blazes like a living flame. Poems by Samuel Taylor Coleridge, Robert Browning, and Sir Walter Scott, among others, have mentioned the aurora borealis; in the 1600s, philosopher René Descartes suggested that sun-

light scattered from ice particles in the upper atmosphere was the cause of the northern lights.

## MAGNETISM

Astronomer Edmund Halley proposed in the early 18th century that the lights were caused by Earth's magnetism. One hundred years later, in 1825, C. Hansteen indicated a link between the lights and geomagnetism. In 1860, Elias Loomis, an American, mapped out the distribution of northern lights geographically and showed that they formed a ring around the North Pole. In his 1881 work *Das Polarlicht*, Swiss physicist and engineer Herman Fritz extended Loomis's research. Both men identified a correlation between the auroras and sun spots, noting that the lights grew stronger and weaker following the 11-year cycle of sunspot activity. In 1896, Norwegian physicist Kristian Birkeland showed with models that electrons from the sun would bend toward the Earth's magnetic poles and enter the ionosphere, where they decelerated and emitted light. Current research shows that the electrons thrown by the sun generate currents as great as a million amperes. This was also proposed by Birkeland, but in 1896 the idea was ignored.

A similar phenomenon occurs around the southern geomagnetic pole and is called the aurora australis.

## Australia

**Map Page** 1126 **Area** 2,967,895 square mi (7,686,850 square km) **Population** 19,731,984 (2003) **Capital** Canberra **Highest Point** 7,311 ft (2,229 m) **Lowest Point** 49 ft (15 m) **GDP per capita** \$27,000 **Primary Natural Resources** gold, silver, uranium.

THE COMMONWEALTH of Australia is the world's sixth-largest country and is located on the world's smallest continent between the INDIAN OCEAN and the South PACIFIC OCEAN. The countries surrounding Australia are NEW ZEALAND to the southeast, PAPUA NEW GUINEA to the northeast, and INDONESIA and EAST TIMOR to the north. Australia is a democratic federation under the Commonwealth of Nations, which recognizes the British monarch as the head of state, who is represented through the governor-general. Australia is divided into six states and two territories, including the island of Tasmania. The legislature is a bicameral federal parliament that provides popular and state representation. The prime minister serves as the head of government.

Australia is roughly the size of the continental UNITED STATES. Due to millions of years of erosion, its coastline is generally even, with few indentations. Constant wind and water erosion give Australia the distinction of being the flattest continent. Australia's interior consists of the Great Western Plateau, the Central Lowlands, and the Eastern Highlands. Much of the Great Western Plateau is desert, particularly, the Great Sandy Desert, Gibson Desert, and Great Victoria Desert, where much of Australia's mineral wealth is located. The Central Lowlands contains the Great Artesian Basin, which holds 670,000 square mi (1,735,300 square km) of underground water. The Great Artesian Basin serves as pasture land for Australia's traditional sheep ranching industry. The major cities of Australia are located in the Eastern Highlands, along the eastern and southeastern coast, which consists of plateaus, hills, and low mountains.

Australia's climate, while it varies greatly, does not suffer extreme temperatures because it lacks physical barriers. Beyond its northern coast is the GREAT BARRIER REEF, one of the great natural wonders of the world, which is in danger from pollution. The climate is generally arid to semiarid. In the north, the climate is tropical, while temperate in the south and east. The tropical region has a hot and rainy season from February to March and a warm dry season. The deserts in central and western Australia receive only 10 in or 25.4 cm of rain. Because of Australia's position in the Southern Hemisphere, the seasons occur opposite to those experienced in the Northern Hemisphere. In the south, January and February are the hottest months, with temperatures averaging between 65 and 70 degrees F (18.3 and 21.1 degrees C). June and July are the coldest months, with temperatures averaging 50 degrees F or 10 degrees C.

The first humans who settled in Australia came over from a land bridge that once connected Australia to Asia. The Aborigines, who are the descendants of those first settlers, are a hunter-gatherer society that roamed about the land. They spoke about 250 languages and all of their property was communal. Before the arrival of Europeans, Aborigines numbered between 250,000 and 1 million.

The first European to sight Australia was Captain James Cook in 1770. He circumnavigated the Australian coast and landed in Botany Bay, claiming the land for Britain. After the loss of the thirteen North American colonies, the British government saw Australia as a new destination to which it could send convicts. In 1787, the First Fleet, under the command of Captain Phillip Arthur, set sail from Portsmouth, England, to Australia, consisting of 11 ships carrying 1,487 people, of whom 736 were convicts whose crimes were mostly petty theft. In January 1788, the First Fleet landed on what became Sydney Harbor. The penal settlements of New South Wales, Van Diemen's Land (later Tasmania), and Port Phillip District (later Victoria) were established, while Western Australia and Southern Australia were created as free settlements.

In 1851, gold was discovered in Victoria, sparking an influx of immigrants from all over the world. The population grew from 450,000 in 1850 to 1 million in 1858. The effects of the gold rush were the growth of national wealth, a spirit of egalitarianism, and the spark of nationalism.

By the end of the nineteenth century, Australia evolved from penal settlements to self-governing units where settlers took part in local affairs. In the 1890s, Australia was at a crossroads in its relationship to the mother country. Some circles called for independence from Britain, while others called for self-government within the BRITISH EMPIRE. Economic forces such as a worldwide depression and increasing unionization called for uniform laws and regulations.

On January 1, 1901, the Commonwealth of Australia was born, which fused British and American models. The Commonwealth would be a parliamentary government like Britain, but it would have a federal system like the United States, where there would be state and popular representation in its legislature. Not long after, Australia gained the distinction of having a progressive government by establishing a minimum wage, ensuring safe conditions for workers, and granting suffrage for women. Yet at the same time, the new government maintained the "White Australia"

policy which limited immigration to Europeans and mostly British.

Australia maintained its loyalty to Britain by contributing troops to the Boer War, World War I, and World War II. Australian troops distinguished themselves bravely during the famous Gallipoli campaign of World War I. However, after the end of the war, the troops who came home had difficulty readjusting to civilian life, partly because of well-meaning but, in the end, inadequate government policies. Australia suffered greatly during the Great Depression of the 1930s, when as much as 28 percent of the workforce was unemployed.

By World War II, Australia's traditional links to Britain and the empire began to weaken. In 1939, Australia sent troops to Europe to fight Nazi GERMANY. However, JAPAN loomed as a larger threat to Australia's security. Australia fell under the protection of the UNITED STATES. After the war, Australia entered into the ANZUS alliance with New Zealand and the United States and began looking to Asia as a source for new markets. In 1972, the "White Australia" policy was replaced with an immigration policy that stressed multiculturalism and accepted immigrants from other areas of the world. In 1999, Australians once again faced the terms of their relationship with Britain, voting whether to keep the queen as head of state or declare itself a republic; a slim majority maintained the status quo. In 2002, after the terrorist bombings at Bali, Australia joined the United States as one of its coalition partners in the war against terrorism, providing troops to Iraq in 2003.

Despite the official end of "White Australia," the population remains generally homogeneous, with 92 percent of European origin, 7 percent of Asian origin, and 1 percent of Aboriginal origin. However, since the end of World War II, Australia has accepted immigrants from eastern and southern Europe, adding to the old English stock. Australia's relationships with the Aborigines have not been easy. European colonialism had wiped out much of the original population through disease and assimilation. While Australians have become more sensitive to the plight of the Aborigines, many have remained at the bottom of the economic ladder.

Australia has a prosperous free market economy that is ranked with western European economies. Services make up 71 percent of the gross domestic product (GDP), while industry makes up 26 percent, and agriculture makes up 3 percent. In 2000, Sydney hosted the Olympic Games, 44 years after its rival, Melbourne.

The Australian economy suffered during the global economic slowdown in 2001, but it has been undergoing a recovery since 2003. In 2004, the Australian government debated whether to approve a free trade agreement with the United States.

## Austria

**Map Page** 1131 **Area** 32,377 square mi (83,858 square km) **Population** 8,188,287 (2003) **Capital** Vienna **Highest Point** 12,457 ft (3,797 m) **Lowest Point** 377 ft (115 m) **GDP per capita** \$25,400 **Primary Natural Resources** natural gas, iron, timber.

**LANDLOCKED AUSTRIA** (Österreich in German) is located at the cultural and geographical crossroads of Central Europe. It is also situated in between the three major cultural spheres of Europe. To the south is ITALY, to the north GERMANY, and to the east several Slavic countries. This relatively small country (about the same size as MAINE) borders no less than eight other countries. Austria itself is overwhelmingly German-speaking and Roman Catholic (although, as is most of Europe, relatively secular in orientation).

Today's Austria was created as what can be described as a historical accident. Before countries, or nation-states, existed in the modern sense, local rulers controlled small territories that sometimes grew to large empires. Seated in Austria, the Habsburg dynasty became one of the most powerful in Europe as early as the medieval era and governed a territory that included parts of today's FRANCE, Italy and Germany. Over time,

the Habsburg empire lost control over some of these western territories and instead expanded eastward, and after 1867 it became the Austro-Hungarian Empire, two separate states under one common ruler. The name Austria then simply referred to the predominantly German-speaking territories, which previously were not considered a coherent territorial unit. The eventual demise of Austria-Hungary was triggered by its involvement in the Balkans. Several European powers struggled for influence in southeastern Europe, which subsequently led to World War I. Austria-Hungary was on the losing side in the war, and along with a rewriting of the political map of large portions of Europe, modern Austria, now a republic, was born in 1918.

What emerged as the state of Austria was several small regions that had some basic cultural attributes in common—language and religion—but nevertheless lacked a distinct national identity. Part of this has to do with Austria's fragmented geography. The most dominant landform is the ALPS—the mountains that cover the entire western portion of the country and stretch deep into central Austria. Like many populations that inhabit mountainous areas, the Alpine dwellers have historically been localist in their orientation rather than identifying with a larger nation. The remaining parts of Austria are lowland and river valleys, more populous, and dominated by the capital of Vienna. As Austria has been a state for almost a century, national media, a national educational system, and other nationwide institutions have created a greater sense of common identity over time.

Vienna is a classic example of a primate city—a city that dominates in a country in terms of size and political, economic, and cultural importance. Vienna has approximately 1.5 million inhabitants, while the second- and third-largest cities, Graz and Linz, have populations of only approximately 200,000 each. In the 18th and 19th centuries, Vienna was one of the most important cities in Europe, even a world city. As the capital of a large multi-ethnic empire, the city became a diverse political and economic power thriving on immigration from both German and non-German regions. This diversity also made Vienna an intellectual and creative center in many divergent endeavors, such as philosophy, arts, and economics.

The power of Vienna during this time period is also reflected in its impressive environment, with its beautiful baroque and other architectural styles, which attracts many visitors. Vienna is located on the DANUBE (Donau in German) that flows from Central Europe eastward to the BLACK SEA, a convenient location his-

*St. Stephen's Cathedral in Vienna is one reason why the capital is also Austria's primate or dominant city.*

torically, as well as centrally located within Austria-Hungary. Today, Vienna's eastern location near the Slovak border is peripheral within Austria. Facing the Iron Curtain, it was also far away from the population centers of western Europe during the Cold War and lost population. In the future, however, Vienna and Austria hope to capitalize on its proximity to the growing markets of eastern Europe.

Austria was economically prosperous during the post-World War II period, much like the rest of western Europe. Today, the economy is increasingly service-oriented, including the largest tourist economy per capita in Europe. There is, for example, one guest bed for

every six Austrians. Both summer and winter tourism is common in the Alps, with the latter growing in importance. Visitors arrive from many countries, but Germany has always been the leading source of tourists. The tourism industry is also one reason behind the long-standing trend of population growth in western Austria at the expense of eastern Austria. The Alpine landscape is not only utilized by foreign visitors, but skiing has become the nation's favorite recreational activity and has produced outstanding national sport heroes, most recently Hermann Maier.

Tourism has changed rural life, but it has also made it possible for part-time farmers to survive. The Austrian government (and now the EUROPEAN UNION, which Austria joined in 1995) also extends economic support to farmers to preserve a traditional, small-scale agricultural landscape. On the negative side, avalanches are one of the otherwise few natural risks in Austria, many lethal to skiers and others, killing dozens every year. Economically, Austria's tourism economy is also facing challenges as European tourists are searching for more exotic and far-flung experiences than the Alps.

Recent trends are changing the social and economic fabric of the country. Global competition is felt in all sectors of the economy. Generous social benefits of the welfare state are increasingly difficult to maintain as the population is aging (while life expectancy is very high, the fertility rate of 1.3 children per woman is one of the lowest in western Europe). Immigration increased in the 1990s, particularly from eastern Europe and former Yugoslavia, leading to a rise in xenophobia and a new right-wing, anti-immigrant political party that upset the traditional consensus and cooperative spirit of Austrian politics. Austria is again struggling with its national identity, its past as part of Nazi Germany, and an increasingly multiethnic society that will shape the country for decades to come.

OLA JOHANSSON  
UNIVERSITY OF PITTSBURGH, JOHNSTOWN

## Azerbaijan

**Map Page** 1121 **Area** 53,820 square mi (86,600 square km) **Population** 7,830,764 **Capital** Baku **Highest Point** 15,551 ft (4,740 m) **Lowest Point** Caspian Sea -92 ft (-28 m) **GDP per capita** \$3,400 **Primary Natural Resources** petroleum, natural gas.

AZERBAIJAN, A FORMER Soviet republic, now officially the Republic of Azerbaijan, is a nation with a Turkic and majority Muslim population. It regained independence after the collapse of the Soviet Union in 1991. It is located in the region of the SOUTHERN CAUCASUS MOUNTAINS, and borders the CASPIAN SEA to the east, GEORGIA and RUSSIA to the north, IRAN to the south, and ARMENIA to the southwest and west. A landlocked nation, Azerbaijan has three dominant physical features: the Caspian Sea, whose shoreline forms a natural boundary to the east; the Greater Caucasus Mountain range to the north; and the extensive flatlands at the country's center. Of the three Transcaucasian states (Georgia, Armenia, and Azerbaijan), Azerbaijan has the greatest land area. A small part of Nakhichevan also borders TURKEY to the northwest. The capital is the ancient city of Baku, which has the largest and best harbor on the Caspian Sea and has long been the center of the republic's oil industry.

The country's elevation changes over a relatively short distance from lowlands to highlands; nearly half the country is considered mountainous. Notable physical features are the gently undulating hills of the subtropical southeastern coast, which are covered with tea plantations, orange groves, and lemon groves; numerous mud volcanoes and mineral springs in the ravines of Kobustan Mountain near Baku; and coastal terrain that lies as much as 92 ft (28 m) below sea level. Except for its eastern Caspian shoreline and some areas bordering Georgia and Iran, Azerbaijan is ringed by mountains. To the northeast, bordering Russia's Dagestan Autonomous Republic, is the Greater Caucasus range; to the west, bordering Armenia, is the Lesser Caucasus range.

To the extreme southeast, the Talysh Mountains form part of the border with Iran. The highest elevations occur in the Greater Caucasus, where Mount Bazar-dyuzi rises 15,551 ft (4,740 m) above sea level. Eight large rivers flow down from the Caucasus ranges

into the central Kura-Aras lowlands, alluvial flatlands, and low DELTA areas along the seacoast, designated by the Azerbaijani name for the Mtkvari River and its main tributary, the Aras. The Mtkvari, the longest river in the Caucasus region, forms the delta and drains into the Caspian a short distance downstream from the confluence with the Aras.

Partly because of the great range of altitude in the country, there is a variety of climate, vegetation, and soil conditions. Climate varies from subtropical and dry in central and eastern Azerbaijan to subtropical and humid in the southeast, temperate along the shores of the Caspian Sea, and cold at the higher mountain elevations. Because most of Azerbaijan receives scant rainfall—on average 5.9 to 10 in (15.2 to 25.4 cm) annually—agricultural areas require irrigation.

Azerbaijan shares all the formidable problems of the former Soviet republics in making the transition from a command to a market economy, but its considerable energy resources brighten its long-term prospects. A continuing conflict with Armenia over the Nagorno-Karabakh region may be an obstacle to economic growth.

JAWAHARLAL NEHRU UNIVERSITY, INDIA

## Azores

THE AZORES IS AN archipelago of nine islands situated in the middle of the North ATLANTIC OCEAN, usually divided in three groups according to geographic proximity: the Eastern Group (Santa Maria and São Miguel), the Central Group (Terceira, Graciosa, São Jorge, Pico, and Faial), and the Western Group (Flores and Corvo). The Azores constitutes, along with Madeira, the only two autonomous regions of PORTUGAL, each with its own parliament and government.

These lush green islands (897 square mi or 2,322 square km, with a population of 241,763) are the peaks of an oceanic mountain chain, and their volcanic

origin is associated with the clash of the American, European, and African tectonic plates. The area is subject to frequent EARTHQUAKES and has current manifestations of volcanic activity with geysers and sulfur springs. The latest eruption occurred in 1957–58 on the island of Faial. On several of these islands, volcanic cones have collapsed originating rings of landforms called caldeiras.

### PORTUGUESE SETTLEMENT

It is assumed Diego de Silves was the first to explore these uninhabited islands in 1427. Their combination of fertile soil, abundant water, and mild climate contributed to a successful settlement by the Portuguese in 1443. Most of the land is hilly and covered by cropland, pastures, and forests of introduced cryptomeria conifers and acacia trees and native cedars and dogwood. Because of the proximity of the GULF STREAM, the climate is humid and temperate, with an abundance of rain throughout the year. However, weather can vary widely during the course of a single day.

Until recently, the regional economy depended on an export-oriented agriculture, subjecting the islands to alternating cycles of prosperity and decline according to external demand for their products. Main commodities have included oranges and sugarcane, with corn replacing wheat as the main cash crop at the end of the 19th century. Cattle grazing became the main agricultural activity around the 1960s, as the humid climate favors development of rich pastures. Current regional products include milk, cheese, corn, with tobacco and pineapples on the island of São Miguel and wine on Pico.

The average area of farms is very small (4 acres or 2 hectares), with fields divided by hedges of hydrangeas or azaleas, forming a typical patchwork, which has become a hallmark of the islands. Most of the population concentrates on small coastal towns. The seat of the government ministries and largest city is Ponta Delgada (population 44,000), on the island of São Miguel.

The Azores's islands have benefited from strategic importance since the 16th century, through the age of discoveries to modern times. Because of its central position between North America and Europe, the archipelago has played important role as a resupply outpost during the development of both navigation and aviation. Nevertheless, the isolation led to intense emigration to the UNITED STATES and CANADA and a consequent population decline between the 1960s and 1990s. That tendency has recently reversed thanks to rising living

standards and development, made possible in part by support programs from the EUROPEAN UNION.

PORTUGUESE GEOGRAPHIC INSTITUTE

## Bab el Mandeb

CONNECTING THE RED SEA with the Gulf of Aden and the ARABIAN SEA, bounded by DJIBOUTI, ERITREA, and YEMEN, the Bab el Mandeb is a STRAIT and CHOKE POINT. It separates the Arabian Peninsula from East Africa (HORN OF AFRICA). As its Arabic name implies (“Gate of Tears”), it is a place of worry for any ship’s captain navigating the narrow passage. It has historically been coveted by anyone wishing to control the flow of trade between the MEDITERRANEAN SEA and the INDIAN OCEAN. Egyptian barges, Arab dhows, and Portuguese caravels have all plied this narrowing passage. Each controlling nation has fought others that attempted to wrest it from them.

Britain vied for dominance of the area with both the OTTOMAN EMPIRE and FRANCE. The British seized Aden in 1839 and the Ottomans returned to the northern portions of Yemen in 1849. France focused on the African coast and established the colony of French Somaliland in 1888. With the construction of the Suez Canal in 1869, the increase of shipping made the Bab el Mandeb all the more important. The French remained in Djibouti, while the British departed Yemen and the port of Aden in 1967. Yemen remains an unstable area. In the decade of the 1990s, a full-scale civil war exploded, and internal factions and international terrorist groups launched attacks against government

and commercial targets. The attack on a French-flagged oil tanker by a small boat filled with explosives in October 2002 in the Bab el Mandeb points to continuing concerns.

The Bab el Mandeb is one of the world’s busiest shipping lanes, handling the vast majority of all ocean-going trade between Europe and Asia. An estimated 3.2 million barrels of oil passed through this strait every day in 2000. The Bab el Mandeb is about 17 mi (27 km) wide at its narrowest point between the Arabian and African coasts. The island of Perim sits astride the strait, creating two channels. The eastern channel is known as the Bab Iskender (Gate or Strait of Alexander), which speaks to the ancient lineage of navigation in these waters. This channel is some 2 mi (3 km) wide and about 98 ft (30 m) deep. The western channel has a width of about 16 mi (25 km) and a depth of 1,017 ft (310 m). There are a group of small islands lying just off the African coast.

## Bahamas

**Map Page** 1137 **Area** (land) 1,509 square mi (3,870 square km) **Population** 297,477 **Capital** Nassau **Highest Point** 208 ft (63 m) **Lowest Point** 0 m **GDP per capita** \$17,000 **Primary Natural Resources** timber, salt, aragonite.

THE ISLAND OF San Salvador is cited as the first landing spot in the New World by the explorer Christopher Columbus on October 12, 1492. The small, low-lying chain of islands and cays were then passed over by the Spanish in favor of larger islands and silver and gold on the mainland. Today, however, the independent nation of the Bahamas boasts one of the most prosperous economies and most stable governments in the region, thanks to tourism and its close location to the continental UNITED STATES.

Lying just 90 mi (140 km) off the coast of FLORIDA, the chain includes over 700 islands—only 30 of which are inhabited—plus 2,000 cays. Stretching from northwest to southeast across 600 mi (968 km), the islands have a total of 2,196 mi (3,542 km) of coastline and form a total land area roughly equivalent to JAMAICA. The islands are mostly long, flat coral formations with some low rounded hills.

The main island, New Providence, with the capital city of Nassau, is at the northern end of the chain, between the largest islands in the group, Andros, Eleuthera, Grand Bahama, and Great Abaco. Other main islands include Cat Island, Great Exuma, and Long Island in the center of the chain, and Great Inagua at the southern end. Great Inagua is roughly 62 mi (100 km) from CUBA and 50 mi (81 km) from HAITI. The TURKS AND CAICOS ISLANDS geologically form a southern extension of the Bahamian archipelago but have mostly been administered separately and remain dependencies of the UNITED KINGDOM. The islands of New Providence and Grand Bahama have roughly four-fifths of the population. Most Bahamians live in towns (84 percent, one of the region's highest), either in Nassau or in the other major towns, Freeport (on Grand Bahama) and Matthew Town (on Inagua).

The islands' original inhabitants, the Lucayans (Arawaks), were completely removed to work plantations on Hispaniola and Cuba. Poor soil and few freshwater resources meant that the Bahamas were not

developed as tobacco or sugar plantations like other Caribbean islands, so the islands remained sparsely populated. Settled by British pirates and traders from 1647 onward, the islands became a haven for the most notorious criminals of the Caribbean, notably Blackbeard. The English government tacitly supported raids against Spanish galleons heavily laden with gold bullion. After the abolition of slavery in British colonies in the 1830s, the Bahamas remained a point of slave smuggling and was also home to blockade runners during the U.S. Civil War. This sort of activity became prominent again in a different form in the 1920s and 1930s, when the Bahamas became a chief smuggling center for alcohol into the United States during Prohibition. The economy was again stimulated by the arrival of gambling after the casinos were closed in Havana during the Cuban Revolution (1959).

The Bahamas led the British West Indies in their move to independence, becoming independent in 1973, yet retaining full ties to the Commonwealth and the British crown. Since independence, the government has focused on expanding its industries, primarily in the spheres of tourism and related services, taking full advantage of the country's pleasant, sunny climate, and proximity to the United States. An estimated 3 million tourists visit the islands each year, representing roughly 13 percent of all tourist spending in the Caribbean.

Small local manufacturing industries, including cement, salt, rum, and pharmaceuticals, along with oil refining and transshipment, provide many jobs, but the largest growth area is in development as an offshore financial center, drawing in over 150 major banks from North America and Europe through its specially structured tax and trust laws. Banking and e-commerce are now among the top revenue generators for the government, along with ship registrations (the fifth largest in the world). But the islands continue to maintain their reputation as a haven for illegal activity, becoming once again a center for smuggling into the United States, this time marijuana and cocaine from South America.

## Bahrain

**Map Page** 1122 **Area** 256 square mi (665 square km) **Population** 667,238 **Capital** Manama **Highest Point** 400 ft (122 m) **Lowest Point** 0 m **GDP per capita** \$15,100 (2002) **Primary Natural Resources** oil, natural gas, fish, pearls.

BAHRAIN IS LOCATED in the MIDDLE EAST; it is an archipelago in the PERSIAN GULF, east of SAUDI ARABIA. Bahrain has been the site of human habitation and commerce for millennia. Evidence of active trade between the great hearths of human civilization in Mesopotamia and the Indus Valley are to be found on the islands of Bahrain from as early as 5,000 years ago. Assyrian, Babylonian, Greek, and Persian kings laid claim to this trading center over the ages.

First mentioned in Greek historical sources associated with Alexander the Great, Bahrain continued under its Greek name Tylos until the spread of Islam reached its inhabitants in the 7th century. Regional and foreign powers ranging from the Ummayyad caliphs of SYRIA to the Christian monarchs of PORTUGAL continued to claim and dominate this pearling and trade center until the 18th century. In 1783, the Al Khalifa family seized Bahrain from a Persian garrison controlling the islands and established a ruling dynasty that continues to today.

In the 1830s, the ruling Al Khalifa family entered into treaties with Britain as a protectorate and maintained that status until full independence was declared on August 15, 1971. Bahrain benefited as the first Gulf state to discover and exploit its oil potential beginning in the 1930s, but it never experienced vast oil wealth. Limitations on actual oil reserves within its national borders encouraged Bahrain to develop a more diversified economy that focused on petroleum refining rather than extraction.

Following independence from Britain, the Al Khalifa monarchy experimented with election of a parliament but soon dissolved the National Assembly because of antagonism toward the monarchy and Western allies. The ruling family, the majority of government officials, and corporate leaders are Sunni Muslims. Bahrain's Shia majority (70 percent) was politically disaffected and incidents of political violence were seen in the 1990s, resulting in killings and impris-

onment. With the latest succession within the ruling family, a return to national elections has commenced, along with a general political amnesty. This first national election in over three decades saw a turnout of over 53 percent of eligible voters in the first round and 43 percent in the second round. The latest ruling Al Khalifa has changed his title from emir to king and continues to appoint the upper chamber of parliament as a balance to the lower generally elected chamber.

Bahrain has been the home of U.S. naval operations in the Persian Gulf since 1947 and has provided basing and overflight rights in support of military actions against Iraq since 1990. Bahrain supported the decade of sanctions conducted by coalition forces in support of United Nations mandates against Iraq.

Bahrain's economic diversification provided the Gulf region with an early window to Western financial, telecommunications, and industrial expertise. The region's first oil refinery was built here in 1935 and heralded continual growth of joint ventures that expanded to ship building, metal manufacture, transportation infrastructure, and financial services. Bahrain boasts the presence of many international finance institutions and has created no impediments to their onshore or offshore operations. Bahrain further seeks to become the largest center of Islamic banking in the world. Working toward this goal, it has become a leader in the standardization of regulation for the Islamic banking industry.

Bahrain was quick to invest oil revenues into national infrastructure, health services, and education. Bahrain enjoys the highest adult literacy rate in the region (89.1 percent). The modern communications and transportation network combined with Bahrain's reputation as a relatively liberal and modern Persian Gulf state has added to its desirability as a tourist destination. With its special emphasis on education, Bahrain sees itself as a future provider of higher education in the region. Much financial support and investment has come from gulf neighbors. Saudi Arabia continues to subsidize much of required government revenue by granting oil as aid.

## Baikal, Lake

THE BAIKAL, the world's deepest lake, stretches 391 mi (636 km) long and nearly 50 mi (80 km) wide. On the northeastern borders of central Asia, it lies at an altitude of 1,494 ft (455.6 m) above the PACIFIC OCEAN sea level. With an area of 12,162 square mi (31,500 square km), the Baikal ranks seventh in the world after the CASPIAN and ARAL seas, the North American HURON, MICHIGAN, and SUPERIOR lakes and VICTORIA in Africa.

The lake is surrounded by the vast mountains of the Eastern Sayan massif with an absolute altitude of 11,453 ft (3,491 m). Many of the Sayan mountain rivers flow into the Baikal, like the Irkut and other tributaries of the Angara. The Baikal region is characterized by a continental climate. In winter, the mean temperature falls to 1 to -13 degrees F (-17 to -25 degrees C), the absolute minimum is -35 to -40 degrees F (-37 to -40 degrees C). The mean summer temperature of July, normally the warmest month in the Baikal region, is 66 to 68 degrees F (19 to 20 degrees C), with a maximum of 100 degrees F (38 degrees C).

The underwater slopes of the Baikal depression show a distinct ancient relief of the coastline. Down to depths of 1,640 to 1,968 ft (500 to 600 m), it uncovers submerged mouths of rivers and ancient valleys. About 3.5 million years ago, the Baikal was born by a rift when the Eurasian and Indian plates collided. Tectonically, the lake consists of three deep basins, each separated by underwater uplifts. Winds and changes in the atmospheric pressure have an influence on the water level. The mean perennial level stands normally at 1,494 ft (455 m). The highest level, measured on October 2, 1869, was 1,499 ft (457 m); the lowest, 1,492 ft (455 m), was observed in April 1904.

The first research on the Baikal was done in the 18th century by the German explorers I.E. Gmelin, P.S. Pallas, and I.G. Georgi. Systematical studies on the Baikal were encouraged in the 19th century by the Russian Geographical Society. W. Dybowsky distinguished in 1912 two complexes of the Baikalian fauna: the general Siberian fauna and the endemic fauna. In response to the ecological conditions, these two species are developing completely differently. Ordinary Siberian fauna do only colonize the areas of mild temperatures, that is, near the shores. In contrast, indigenous Baikalian fauna can be found in the depth of the lake. Therefore, the temperature of the water presents an ecological barrier. The greatest enigma for scientists is the presence of seals in Baikal. Alexander VON HUMBOLDT suggested in 1843 that the presence of seals in

the Caspian Sea and the Baikal was evidence of a past connection between these two lakes.

The German explorer O. Peschel believed in 1878 that Baikal was directly connected with the Arctic Ocean and that seals migrated from the north. Others, like V.P. Garyayev (1901) and German paleontologist M. Neimeier (1886), thought that the fauna of Baikal was a relict of an old marine fauna. The Baikal environment is very sensitive to ecological changes. When in 1957 the Soviet government planned to build a cellulose plant at Baikal'sk, local scientists, citizens, and writers like Valentin Rasputin launched a protest campaign that succeed after thirty years. In April 1987, the Soviet government issued a decree protecting Lake Baikal. Nevertheless, the cellulose plant is still producing industrial waste and dumping it into the lake.

## Baikonur

BAIKONUR IS THE former Soviet Union's primary space launch facility. In the early days of the Soviet space program, rockets were launched from Kasputin Yar, a small field in the lower VOLGA RIVER basin not far from Stalingrad (modern Volgograd). However, this launch facility had numerous problems. Mists rising from the Volga River frequently delayed or altogether prevented scheduled launches. The flight path went over several settled areas, raising significant safety concerns if a rocket were to fail catastrophically in atmosphere. Worse, launches could be monitored by an American base in nearby TURKEY, an unacceptable situation to a government for whom security was considered essential.

As a result, the Soviet government decided to create a new, larger base in a remote, secure area that would still be accessible by rail and water links to the industrial centers of the western Soviet Union. Construction began in June 1955 near the village of Tyuratam in the Kazakh Soviet Socialist Republic (one of the 15 constituent republics of the Soviet Union), not far from the ARAL SEA. The Soviet government acknowledged the

launch facility's existence in 1961, but in the secrecy of the time, called it the Baikonur Cosmodrome, after the railroad town of Baikonur nearly 239 mi (385 km) away. Western journalists were not permitted to visit the 600-square-mi (1,554-square-km) facility until 1989, under Soviet leader Mikhail Gorbachev's program of glasnost or openness.

### COSMONAUT'S WALK

The base complex started as a cluster of low, white buildings and concrete blockhouses on the sandy desert, an environment more reminiscent of the American White Sands test range of NEW MEXICO or the rocket test stands of Edwards Air Force Base in CALIFORNIA than the oceanfront vistas of Kennedy Space center at Cape Canaveral, FLORIDA. The equipment in the underground control center was reminiscent of those used on Mercury launches; bare-bones oscillographs, radar scopes, and the like with little in the way of advanced computer technology. The original Baikonur launchpad included an enormous four-part service structure that surrounded the rocket. Interestingly enough, the elevator stopped somewhat short of the top, so that technicians and cosmonauts going to the capsule had to climb a set of steps known as the "cosmonaut's walk."

The technicians and scientists working at Baikonur lived in nearby Zvyezdograd (Star City). This medium-sized town was a purpose-built settlement of the sort the Soviets often created near a major project to house its workers. Zvyezdograd is often lumped together with the cosmodrome proper as Baikonur.

The original Sputnik satellite was launched from Baikonur, as were many other important satellites and all the Soviet Union's manned launches. The Buran space shuttle was also launched from here in its single remote-controlled flight and was brought to land on the cosmodrome's landing strip. (It has subsequently been taken to Moscow and turned into an amusement-park ride.)

In a long-standing launch tradition, all Soviet and post-Soviet Russian rockets are always rolled out of their assembly building at 7 A.M. local time, commemorating the hour the Vostok rocket was rolled out for Yuri Gagarin's historic flight on April 12, 1961, in which he became the first human being to fly in space. Unlike U.S. rockets at Kennedy, Russian rockets are transported horizontally on a special rail car and are cranked upright at the pad.

Following the 1991 dissolution of the Soviet Union, Baikonur belonged to the newly independent

republic of KAZAKHSTAN. Nursultan Nazarbayev, the new president of Kazakhstan, founded the Kazakh Institute of Space Research to coordinate with Russia in operating the Baikonur Cosmodrome. Russian economic problems have led to serious deterioration of the facilities, and most of the personnel are aging, as no younger scientists and technicians have been hired. However, following the February 1, 2003, crash of the U.S. space shuttle Columbia and the grounding of the remainder of the shuttle fleet, the Russians bore the full burden of launches to keep the International Space Station manned and operating, in spite of severe economic difficulties.

## Balkhash, Lake

LOCATED IN eastern KAZAKHSTAN, Lake Balkhash is the world's sixteenth-largest lake, covering a surface area of about 7,000 square mi (18,000 square km); however, its size is being reduced by overutilization of streams that flow into the lake. Closed, with no outflow, Lake Balkhash, like the ARAL SEA at the opposite end of Kazakhstan, has suffered from misuse of water resources. Both have been slowly shrinking for years in area, depth, and volume. Now, in independent Kazakhstan, the lake has fared little better than it did in Soviet times.

Within a complex mountainous drainage basin, Lake Balkhash is fed mainly by the Ili River, as well as by the Karatal and Aqsu rivers. While these streams have long been used for a variety of needs in this arid and seasonally cold watershed, in recent decades developments have caused reductions of stream flow into Lake Balkhash. One major withdrawal has been the filling of the Kapchagay (Qapshaghay) Reservoir on the Ili River. More broadly, the growing population in western CHINA has placed additional demands on the

headwaters of the Ili River. The mountainous location of the source of the Ili River in western China instead of in eastern Kazakhstan has significantly complicated any potential resolution of environmental woes of Lake Balkhash. This negative externality requiring international negotiations over water flows includes about 15 percent of the watershed for Lake Balkhash.

With these and other concerns about water supply, officials at the United Nations Development Program have issued warnings that the lake could dry up to an extent similar to that of the Aral Sea. Kazakh statistics indicate that a surface area reduction occurred by 2003.

### AGRICULTURAL PRODUCTION

On the Kazakh side of the border, water from the lake and its tributaries long has been withdrawn for municipal, agricultural, and industrial uses. Irrigation in Kazakhstan continues to be prominent in this rural region. Ironically, agricultural production has fallen significantly since the 1990s, but water usage remains at the same levels because of artificially set nominal prices for water.

A major example of industrial use has been the copper mining, smelting, and refining industries in and near the city of Balkhash, along the northern shores of the lake. The third-largest copper producer of the Soviet Union, the city, through its smelting plants, annually emits some 80,000 tons of particulate matter. This effluent, in addition to the natural sediments carried in the river inflows, has caused considerable sedimentation of the lake, which now is separated into eastern and western parts, divided by a sandbar. The western portion of the lake is slightly larger by surface area (58 percent), but shallower (only 46 percent of volume).

While Lake Balkhash generally is considered a saline lake, though mildly so, the eastern portion of the lake has increased in salinity more than the western side. With greater freshwater inputs to the west and with limited exchange of water between sides, the eastern waters have progressively differed more and more from the western portion. Environmental damage to the lake's waters also has reduced fish catch, so that amelioration of the problem was sought by introduction of exotic fish species from other parts of the former Soviet Union. This tactic has had mixed results, with some exotic species dominating native species.

JOEL QUAM  
COLLEGE OF DUPAGE

## Baluchistan

BALUCHISTAN, A SOUTHWESTERN province of PAKISTAN, extends from the Gomal River in the north-east to the ARABIAN SEA in the south and from the borders of IRAN and AFGHANISTAN in the west and northwest to the Sulaiman Mountains and Kirthar hills in the east. In its continuity to the west lies Iranian Baluchistan. The land of Baluchistan is exceedingly inhospitable; geologists have even compared the landscape with Mars.

Baluchistan can be divided into two distinct regions. To the northeast, hedged in between Afghanistan and the Indus plains, stretch long ridges of rough highlands. The average breadth of this highland lobe is 150 mi (241 km), but in the north it narrows to less than 100 mi (161 km) along the Gomal River. This area is bounded by the Sulaiman range on the east and the Toba-Kakar range in the northwest. The main central range of Sulaiman, decreasing in height from north to south, forms the dominant geographical feature of the northeast Baluchistan. This region is mainly inhabited by an ethnic group, the Pathans.

The highlands of Sarawan and Jhalawan in Kalat is a block of territory measuring about 300 mi (483 km) by 300 mi (483 km), which is primarily the home of the Brahui and the Balochi, but with a great variety of physical conditions and inhabitants. The Hab River between the Pab and the Kirthar ranges, the Purali or Porali, draining the low-lying flats of Las Bela, the Hingol, and the Dusht in Makaran are all considerable streams, draining into the Arabian Sea and forming important arteries in the network of internal communications. Between southwestern Baluchistan and the northeastern lobe is the wedge-shaped Kachhi plain, which is a land of dust storms and violent winds. Here temperature does not fall below 100 degrees F (38 degree C) in summer and drops below the freezing point in winter.

The mountain ranges of Baluchistan are formed of Cretaceous and Tertiary beds, forming part of an extensive system of Tertiary (Alpine-Himalayan) times.

Besides the Cretaceous and Tertiary beds, Jurassic rocks occupy considerable areas of Baluchistan. With the exception of the Upper Cretaceous and lower Tertiary, especially in northwestern Baluchistan, there is an extensive development of volcanic tuffs and conglomerates probably contemporary with the Deccan traps of India. The sharp bends of the hill ranges around the Kachhi plain have contributed to the instability of this area and have made it seismically important; Quetta was subjected to violent EARTHQUAKES in 1931 and 1935.

Excluding the coastal strip in the south, Baluchistan has a subtropical continental climate marked by extremes of temperatures and aridity. Kachhi and the Chagai-Kharan areas are two of the hottest and driest regions of the subcontinent.

The annual rainfall on the whole is less than 8 in (20 cm), increasing to about 15 in (38 cm) at Shahring in the northeast and falling in the northwest to less than 3 in (7.6 cm). Most of the rain occurs in winter as a result of western disturbances. Summer rains from the monsoons are important only in the northeast. The coast has moderate temperatures and low rainfall and is dominated by a steady inflow of sea breeze in summer.

The region is scant in vegetation and most of the hills are bare of forest growth. On the plains and lower highlands, trees and herbs are conspicuously absent, and the bare stony soil supports a jungle of stunted scrub, the individual plants of which are almost all armed with spines, hooks, and prickles of diverse appearance. In the upper highlands, the vegetation is extremely varied according to local conditions.

Nothing is known about the area until the time of Alexander the Great, whose armies crossed Las Bela and Makaran from east to west in 325 B.C.E. Later, the area probably passed under the control of Parthians and later to the Kushan dynasty. About this time, Buddhism flourished in Baluchistan. In 707 C.E., Mohammed bin Kasim captured various strongholds in Makaran, advanced into Sindh, and established the Muslim power in the Indus valley.

From 1595 to 1638, the province formed part of the Mughal Empire. The Balochi, who gave their name to the province, are comparatively recent arrivals. They apparently entered Baluchistan in the 11th and 12th centuries, being driven out of Persia by the Seljuks. Their rivals, the Brahuis, who occupy the highlands of Sarawan and Jhalawan in Kalat, are of Dravidian stock. The British control ended in 1947 and Baluchistan became the part of independent Pakistan.

## Bangladesh

**Map Page** 1123 **Area** 55,126 square mi (133,910 square km) **Population** 138,448,210 (2003) **Capital** Dhaka **Highest Point** 4,035 ft (1,230 m) **Lowest Point** 0 m **GDP per capita** \$350 **Primary Natural Resources** natural gas, arable land, coal.

BANGLADESH HAS been an independent country since 1971, when it seceded from PAKISTAN in South Asia. Prior to Muslim occupation (1203), its people were believers of Hinduism and Buddhism. With British colonization since 1757, Western influence included a British educational system and the introduction of English, which even today remains the language of the elites. The BAY OF BENGAL lies to the south, INDIA is to the east, west, and north. It has a limited boundary with MYANMAR (Burma). Ninety-eight percent of Bangladeshis speak Bengali (Bangla), the national language; 83 percent are Muslims and 16 percent Hindus.

Three major rivers of the country are the GANGES, Brahmaputra, and Meghna. They discharge an enormous amount of water to the Bay of Bengal, only surpassed by the AMAZON and CONGO rivers. The southern part of the country consists of a DELTA formed by the confluence of the Ganges and Brahmaputra rivers. North-central and southeastern parts are mountainous.

Most of the country is low-lying and riverine and susceptible to flooding during the rainy season, which starts in June and lasts until the beginning of October. Its tropical monsoon climate is erratic; some years cause heavy rainfall; some are normal or have occasional draughts. Its annual rainfall averages 60–80 in

(152–203 cm). Floods and occasional droughts ravage the country, bringing about misery. Cyclones (hurricanes) originating from the Bay of Bengal just before and after the rainy season, cause heavy damage in the southern part.

Because of high rural population density, land is intensively cultivated. As one of the most densely populated countries of the world, Bangladesh suffers from severe overpopulation: 80 percent of country's labor force is employed in agriculture. Rice is the principal food crop; rural Bangladeshis often eat three meals of rice every day. A third of Bangladeshis live below the poverty line. Dhaka, with an estimated population of about 12 million, is the capital and pacesetter of the country. Since its independence and the assassination of the founder of Bangladesh, Sheikh Mujibur Rahman (father of the nation), in 1975, the country has alternated democracy with military dictatorships.

## Barbados

**Map Page** 1137 **Area** 168 square mi (431 square km)  
**Population** 277,264 **Capital** Bridgetown **Highest Point** Mount Hillaby 1,109 ft (336 m) **Lowest Point** 0 m  
**GDP per capita** \$14,500 **Primary Natural Resources** petroleum, fish, natural gas.

BARBADOS IS ONE of the clearest success stories of the CARIBBEAN SEA, with one of the most prosperous economies and stable governments in the region. Having one of the highest population densities in the world (1,548 per square mi), Barbadians were also one of the first nations (in 1955, second only to INDIA) to implement a family planning program, which has resulted in one of the lowest birthrates in the Western Hemisphere. Much of the current population growth is due to the return of Barbadians who emigrated to the

UNITED KINGDOM (UK) in the 1950s and are now retiring back home. For most people in 18th-century Britain, Barbados was the Caribbean—British settlers had been on the island since 1627; its main town, Bridgetown, was a large, bustling trade city, and the colony had become the largest and wealthiest of all the English colonies, surpassing VIRGINIA and MASSACHUSETTS. The colony had over 40,000 English residents, and one of the oldest legislatures in the New World.

Lying about 100 mi (161 km) east of the main arc of the Antilles, the island was usually the first port of call for Europeans crossing the ATLANTIC OCEAN. The Portuguese had first named the island “bearded ones,” after the bearded fig trees they found there. There were no original inhabitants at first encounter, so there was no resistance to overcome for the great number of planters who came to set up small farms for tobacco, cotton, and indigo.

The land is relatively flat, with a gentle rise to a central highland. As part of the eastern arc of the Antilles (including Antigua, St. Martin, and ANGUILLA), any volcanic activity is much more distantly removed, and the older, more weathered soil, is very rich and commercially viable on a large scale, especially in the central highlands. The “sugar revolution” of the 1640s to 1680s thus began here and ultimately changed the overall economy of most of the region. As small farms were replaced with large plantations, most English landowners were squeezed out by the sugar barons and resettled in the Guianas and SOUTH CAROLINA, replaced by large numbers of slave laborers imported from Africa. Barbados was the center of the sugar-producing world until the abolition of slavery in 1834, but the industry continued to dominate, run both by freed Africans (the majority of the population), and some descendants of white laborers (called “Red Legs”).

Barbados was one of the first British colonies to achieve independence, in 1966, with one of the easiest transitions to self-rule. It remains an active member of the Commonwealth, with the British monarch continuing to serve as chief executive. Production and export of sugar have declined in the past 30 years, but locally produced rum remains a specialty. Agriculture has become more diverse, producing more vegetables and fruits for domestic consumption, but much of its food is still imported. More than 80 percent of the population is employed in service industries, mostly tourism. Tourists generally come from the UK, not from the UNITED STATES, so Barbados retains its British style in many ways more than its Caribbean neighbors (the closest being St. Vincent and the Grenadines). There is

a growing U.S. presence in the data processing industry, taking advantage of the very literate Barbadian population (99 percent).

## Barcelona

BARCELONA IS THE second-largest city in SPAIN after MADRID and is the capital of the autonomous region of Catalunya/Cataluña (Catalonia), which is situated in the northeast of Spain. The region is bordered to the north by the PYRENEES mountain range, which acts as a natural border between Spain, ANDORRA, and FRANCE; to the east the region is bordered by the MEDITERRANEAN SEA; to the west by the region of Aragon; and to the south by the Valencia region.

The metropolitan area of Barcelona has a population of approximately 3 million citizens, although only about 1.6 million of this total reside within the bounds of the city proper. The city comprises a number of distinct districts, each with its own character and urban form, which includes Cuitat Vella, the old city area, the 19th-century Eixample/Ensanche (extension), Montjuïc, Sarrià, Gràcia, and new districts (Nou Barris) such as Trinitat Nova at the city periphery. As a consequence of these different districts, it is possible to walk by Roman remains, medieval buildings, and modern developments within a short space of time, particularly if walking westward from the low-lying seafront areas such as Barceloneta or Barri Gòtic (Gothic district) to the hills surrounding the city.

Like many other settlements in Spain and Europe, Barcelona has a long history, and the Romans were significant to its early development. Today, the outline of the Roman Forum can still be seen in the center of the city, and parts of the city walls built by the Romans also remain. During its history the city has been controlled and fought over by a number of different peoples, including the Visigoths in the 5th century, the Frankish Kings of the 9th century, and the Muslim statesman Al-Mansur in 985. The golden age of

Barcelona as an economic and cultural power, however, dates from the late 19th century, although its development was late when compared with other European cities in England and France.

Nonetheless, upon the tearing down of the medieval city walls in the mid-19th century, the city for the first time was able to develop at a rate never seen before in its history. But this removal of the city walls was in part necessary because of the cramped, disease-ridden conditions of the old city and the fact that the lack of space also hindered its growing industrial base. Therefore, with the removal of the city walls, Barcelona was able to spatially, economically, and culturally expand itself, and this legacy comprises vast sways of the city's urban form today.

For example, the huge district known as Eixample, laid down to a plan by Ildefons Cerdà (1815–76), not only transformed the old settlement but remains a major element of the modern city today. Characterized by its geometrically formed grid crossed by wide avenues, the Eixample was a pioneering urban project within which considerations were made for traffic circulation, sunlight, and ventilation in the houses built within square-shaped blocks (the corners of which are rounded).

Within this large district are found many of the city's most beautiful buildings as well, including numerous edifices by renowned architect Antonio Gaudí who designed largely in Gothic inspired and an art nouveau style. Among the most prominent of Gaudí's works in the Eixample are the Casa Batlló, Casa Milà (La Pedrera, the "quarry"), and La Sagrada Família (The Holy Family, from 1884), probably the city's most famous symbol after its football team, Barcelona Football Club. Gaudí's legacy in the city today forms an integral part of the city's tourist industry, and tourists from all over the world come to the city to marvel at his work and also the city's rich culture, which includes museums of the modern artist Joan Miró and the father of cubism, Pablo Picasso.

In recent times, Barcelona has become synonymous with international sporting and cultural events, such as the 1992 Summer Olympics and the 2004 International Forum of Cultures, and many people see these events as integral elements in the development of the city and its economy. In reality, Barcelona has a tradition of hosting famous events that dates from 1888, when it held the Universal Exposition; this tradition was continued into the 1920s with the World's Fair, an event in which Ludwig Mies van der Rohe helped develop modernist architecture through the design of his

Pavilion building. Nonetheless, these events have helped architecturally, economically, and culturally shape the city and its urban form, the result of which is a vibrant, cosmopolitan center today that inspires both eye and mind.

## basaltic flows

THE WORD *basalt* is said to have an Ethiopian origin, meaning “black stone.” Basalt is a dark gray to black, dense to finely grained igneous rock that is the result of lava eruptions. Basalts are not only the most abundant lavas, but they are also the most voluminous. Basalt, when exposed to the air, becomes covered with a brown crust, consisting largely of oxides of iron. The continental masses are mainly built up of granite material, but at some places they are injected with or penetrated by material of greater density from the layers below. These lower layers may be the source of the great basaltic extrusions on the Earth’s surface. Basalt flows are noneruptive, voluminous, and characterized by relatively low viscosity. They generally advance less than one mile or kilometer per hour on gentle slopes and may reach more than 30 mi (50 km) from their source or erupting vent.

A lava flow is defined as the product of a single eruption that may be divisible into one or more flow units, which represents a single pulse or surge of lava that flowed away from the eruptive vent and then cooled separately. The length of the lava flow is determined largely by the magma effusion rate. Basalt lava flows that originate from fissures spread for distances that are roughly proportional to the third power of their thickness.

These lava flows are called flood basalts because a large volume of lava erupted in a short period of time. Each flood of lava has its own unique chemical composition. The dark area that forms part of the moon’s face is a flood basalt eruption. Flood basalt regions exist on every continent. In plains basalt provinces such as Snake River and ICELAND flows are much less than 1

cubic mi or km. Basaltic lava flows in HAWAII extend for more than 21 mi (35 km) with an average thickness of 16 ft (5 m). Andesite flows have higher viscosity and few extend more than 9 mi (15 km). One andesite flow of Pleistocene age in the Cascade range is 50 mi (80 km) long. One Icelandic basaltic flow reached 93 mi (150 km).

## FISSURE ERUPTIONS

In the past, fissure eruptions have taken place on a gigantic scale. The basaltic lava of the Deccan Trap in INDIA, and the lava flows of the Snake River Plains in the UNITED STATES, appears to have been poured out from fissures. The basalt flows of the northeast of IRELAND and in Skye, Mull, and other islands of the Hebrides are of a similar type, and are merely the remains of an enormous lava field that probably extended as far as GREENLAND. The flows apparently came from fissures. In western OREGON and western IDAHO, the lava spilled out of giant fissures in the Earth’s crust that stretched for more than a 100 mi or km during a period from 15 to 17 million years ago covering an area of 20,000 square mi (52,000 square km). Hundreds of such flows were erupted in this region. The basalt oozed in large quantities from fissures. Some examples include the following.

The Deccan Trap, an extensive area in western and central India, has been covered with basaltic lavas. The horizontality of the lavas has resulted in the formation of flat-topped plateaus at different elevations with either steep walls or terraces on the lower flows. These have a steplike arrangement. In the area east of the Western Ghats, the scenery is like that of a country of mesa and buttes.

The Giant’s Causeway, a World Heritage Site in Ireland, is an area of 40,000 tightly packed basalt columns resulting from a volcanic eruption 60 million years ago. Vertical joints form hexagonal columns and give the impression of having been artificially constructed. The columns were formed as a natural consequence of lava cooling. The tallest are about 40 ft (13 m) high. The tops of the columns form stepping stones that lead from the cliff foot and then disappear in the sea.

Columbia River basalt, where the flood basalt flows beneath the Columbia basin, accumulated to a thickness of more than 5,000 ft (1,724 m). Their many layers are clearly visible along the paths of the Snake. The Columbia River plateau was created by a series of basalt flows. It covers more than 62,000 square mi (164,000 square km) of area of the Pacific Northwest.

Over 17 million years ago cracks in the Earth's surface began spewing molten basaltic lava and the basalt floods continued in one form or other, until about 6 million years ago. Much of this lava spread to cover large parts of Oregon and WASHINGTON. Columbia River basalt consists of 270 individual lava flows within an average volume of 135 cubic mi (561 cubic km) per flow. Out of them, 21 poured through the Columbia River gorge. The uniqueness and beauty of the Columbia River gorge is attributed to basalt flows. As the flows flooded the region's lowest areas, they filled canyons and permanently altered the river's path on several occasions. Basalt flows exposed in the walls of the gorge feature a jointing arrangement. These arrangements were created as the lava flow solidified.

On the Snake River plain, the lava flows of the Snake River are complex, in terms both of structure and emplacement processes. Basalt flows consist of long tortuous bodies with many side lobes. Most flows accumulate as small, low shields, fissure flows, or large tube-fed flows.

Flood basalt flows from even earlier times and their impact on the Earth's environment are now being looked at as a possible cause for the extinction of the dinosaurs and other forms of life. The eruption of the Deccan flood basalts in India, ten times larger than the Columbia River basalt, occurred at the time the dinosaurs died out 60 million years ago. These tremendous lava eruptions could dramatically alter the climate, giving rise to the conditions that could have caused mass extinction, common through the history of the Earth.

## bases of trade

**GEOGRAPHIC BASES** of trade are places established for the trade or exchange of commodities and/or the transshipment or warehousing of goods. While a base of trade may develop into a multifunctional adminis-

trative and/or ceremonial center, its original function as a nodal point at the intersection of at least two discreet networks remains the center's primary reason for existence, until that intersection ceases to be of importance for the trading partners.

Scholars of premodern trade (to the early 1800s in industrialized countries) have identified several categories of trading bases, most prominently **ENTREPOTS** or emporia, fairs, solar central places, ports of trade, and gateway communities. While these categories often denote similar sites, they were created by different disciplines to describe the role of the trading base in different disciplinary contexts.

*Entrepots/emporia* and *fairs* are terms used in historical sources and, therefore, by historians. Entrepots/emporia were permanent trading bases, located either in a town's harbor, but physically separated from the town, or as a free-standing colonial trading settlement situated at the border between two distinct ethnocultural zones. Both types were permanent bases administered by port officials to collect tariffs and maintain a peaceful and fair trading zone through special laws for foreign merchants. Although entrepots could operate on a seasonal basis, their primary purpose was trade.

Fairs, in contrast, were generally of short duration, were held at multifunctional centers, and could move cyclically among several such centers over the course of a year. There were three types of fairs, serving local, regional, and interregional trade. Local fairs lasted one to two days, had a small catchment area (30-mi or 48-km radius), transacted a low volume of goods (cattle and salt), and saw small-scale traders selling directly to the locals. Regional fairs could last up to two weeks, had a larger catchment area (up to a 200-mi or 321-km radius), had a higher turnover of goods, and saw merchants buying or selling to specialized producers. Interregional fairs had durations of three to eight weeks, a large catchment area (up to a 600-mi or 965-km radius), and specialized in the sale of luxury items that were carried directly to the fair over long distances. The Champagne fairs of FRANCE are the best-known example of a circulating fair, which began as local fairs, grew into regional fairs for Flemish cloth agents, and eventually became Europe's largest fair circuit for the exchange of cloth and other goods for spices and luxuries brought by Italian merchants from the East.

Economic geographers and anthropologists use other categories to explain premodern exchange systems. The solar central place is used by geographers to describe a site that serves as the center of an interlock-

ing system of lower hierarchical centers. Administered by elites, the central place maximized the exchange of goods by shortening the distance between more distantly dispersed centers in the region.

While central place theory stresses spatial relationships, the anthropological model of the port of trade, developed by Karl Polanyi, places focus on institutional factors. Ports of trade bordered two distinct economic, environmental or ethnocultural zones and operated as “neutrality devices” to facilitate trade between foreign merchants and the host population. Like the entrepot/emporium, a port of trade was founded by a tacit or explicit agreement between foreign traders and the local elites. In order to sustain peaceful trade, however, the long-distance trade occurring at the segregated port of trade could not interfere with the local trade of the hinterland, a criterion that is often impossible to demonstrate with archaeological evidence.

In contrast, the geographical gateway community is a more flexible type, describing a trading base that bordered different mineral, agricultural, and/or craft production zones, was situated on a trade route, and satisfied a demand for trade goods. Administered trade via formal agreements and special foreign merchant laws is not a requirement. Like the port of trade, however, the gateway community was also a monopolistic market, the goods of which were used by elites to maintain their status, whereas the solar central place was but one, albeit the senior, place in a system of points in a multinodal regional exchange system.

Several themes emerge from these models. Bases of trade were not common in the interior of homogenous environmental and economic zones. Peasants in large agricultural zones tended to produce all that was required for a subsistence lifestyle, and therefore had little need for trading bases. Small luxury items were obtained from itinerant merchants. Concomitant with the rise of states, tax- and rent-paying peasants were compelled to sell agricultural goods and livestock at local fairs, held periodically at a nearby center.

By way of contrast, peoples living in marginal environments, such as deserts, arid grasslands, or along coasts that lacked an agricultural hinterland, pursued less diversified forms of subsistence, which necessitated that they trade with neighboring peoples in different economic environmental zones for goods that they could not produce themselves. Central Asian and Saharan desert nomads, for example, brought animal products from their flocks to entrepots/emporia or ports of trade located on the desert’s edge to trade for grain, metals, and fibers produced by local agriculturalists. In

order to maximize their trade at the Savannah entrepots, such as Timbuktu, the Berber nomads of the western Sahara became intermediaries between the Maghreb and sub-Saharan Africa, transporting salt from desert oases to the savannah, where salt was scarce, returning north with gold and ivory. Like pastoral nomads, “aquatic peoples” such as the Bobangi fishermen of the middle CONGO RIVER practiced a limited form of subsistence that needed to be supplemented, trading their surplus fish at points along the river for the yams and manioc of neighboring agriculturalists.

Another aquatic culture, the Greeks, whose terrain was arid, rocky, and better suited to viticulture, established emporia or ports trading colonies on the coasts of the more productive agricultural territories north of the Black Sea, where they exchanged their wine and olive oil for grain. As the more mobile and dependent trading partners, the Berbers, Bobangi, and Greeks brought their goods to agriculturalist markets, becoming middlemen as well for exchange between more distant markets.

## DEEP HARBORS

Changes in transport technology and the emergence of rival networks influenced the location of trading bases as well. As the volume of trade increased in northeastern medieval Europe, entrepots/emporia with shallow harbors were bypassed for deep-harbored trading settlements that could accommodate heavier cargo vessels. Advances in ship-building technology and the greater use of Mediterranean sea routes cut the cost of luxury trade with the East, causing the decline of the Champagne fairs, which depended on expensive overland routes. When ships became the dominant medium for commercial transport from the 15th to the 18th centuries, coastal sites were the main centers for inter-regional trade, such as Hormuz (PERSIAN GULF) and Gao (western INDIA) for the INDIAN OCEAN trade. The importance of overland bases returned in the 19th century, however, as new fairs and entrepots/emporia were established along railroad lines, such as Irkutsk and Vladivostok, which functioned as waystations for the Trans-Siberian Railroad. Attracting permanent populations from western Russia, the Trans-Siberian trading bases quickly evolved into administrative and political centers.

With the modern global economy based on brokerage and credit, bases of trade are now increasingly less determined by geographic location. While port and airline facilities are still important, the presence of bank-

ing and stock market facilities, such as those in NEW YORK CITY, LONDON, and TOKYO, are of prime importance for sustaining an interregional center.

## basin

BASINS ARE LARGE-SCALE depressions in the land surface or seafloor. Their sides may dip gently or steeply, but their bottoms are always wider than they are deep. Streams flowing into basins often fill their floors with sediments. Lakes typically occupy lower parts of the basins on land, thus they may fully emerge as lakes dry up. The largest water-filled basins are ocean basins—the PACIFIC, ATLANTIC, and INDIAN ocean basins. Basins exist because of land erosion or structural geology.

Three agents of erosion are prolific creators of basins on land—rivers, glaciers, and groundwater. Rivers form large drainage basins by eroding mountainous areas through tentacle-like systems of incising tributaries. The MISSISSIPPI-Missouri River and the Ohio River basins are examples of this basin type. Glaciers create basins by plucking (quarrying) huge chunks of rock as they move over underlying bedrock. They reveal the basins after they melt back during warm periods. The size of glacier basins varies considerably. The now extinct Laurentide ice sheet created the Hudson Bay Basin in northern CANADA.

In the continent's midsection, the same glacier quarried the Great Lakes basins and the smaller but impressive Finger Lakes basins in upstate NEW YORK. Former alpine glaciers scoured even smaller basins—cirque and rock basins that are scattered throughout the ROCKY MOUNTAINS, HIMALAYAS, ALPS, and other high Alpine regions. Groundwater (or water underground) also creates basins. The cool water is acidic and dissolves limestone to create a Swiss-cheese network of

underground solution channels and subsurface caves. Over time, a cave roof collapse creates increasingly larger basins, which geomorphologists call dolines and uvalas. These solution basins are typical of KARST regions (areas whose landforms develop by solution in limestone).

Oceanic, intermontane, fault block and synclinal basins are results of rocks that subside, warp, fold, or break. The shape, size, and topography of oceanic basins are results of all these movements. Ocean basins have many structural sub-basins that collect thick, undisturbed layers of fine-grained deposits. On land, the largest basin is the intermontane basin, a broad area enclosed by higher landforms. The Great Basin region, which sits between the Pacific Mountain System and the Rockies in the western UNITED STATES, is a good example.

A third basin type—the synclinal basin—is composed of downfolded layers of sedimentary rocks. The LONDON or PARIS basins are examples. Synclinal basins can be important, as they fill with sediment and thereby help preserve any layers of coal beneath, such as in the Saar Basin in FRANCE, the Donets Basin in UKRAINE, or the Wyoming Valley in PENNSYLVANIA. The smallest basin is the fault block basin (graben), which is typical of basin-and-range terrain. Vertical displacement along the faults (normal faulting) creates the basin. The Great Basin region has numerous fault block basins and intervening ranges.

RICHARD A. CROOKER  
KUTZTOWN UNIVERSITY

## Bay of Bengal

THE BAY OF BENGAL is a triangle-shaped water body, which is an extension of the INDIAN OCEAN to the north. It is stretched over an area of 5.7 million square mi (14.7 million square km) with an average depth of approximately 8,530 ft (2,600 m). Countries that surround the bay are SRI LANKA, INDIA, BANGLADESH,

MYANMAR (Burma), THAILAND, and MALAYSIA. West Bengal and Bangladesh are located at the extreme northern end of the Bay of Bengal, and gave the bay its name. The cyclones (hurricanes) originating in the Bay of Bengal, usually before or after the rainy season, devastate the southern part of Bangladesh regularly, and occasionally they affect the West Bengal state of India and Myanmar. The bay has a significant importance in the daily life of the coastal people because it is a great source of fishing: Both sail boats and trawlers operate in the bay.

The Bay of Bengal is an extensive and wide U-shaped basin that opens to the Indian Ocean. The base of the basin is a gently sloping southward plain dissected by sub-aqua valleys, trenches, and ridges. The bottom topography is prominently marked by the Java trench, Ganga trough, Ninety East Ridge, Eighty Five Ridge and Bengal Deep Sea Fan. The Bay of Bengal is dotted with numerous islands, including Andaman and Nicobar, Union Territory of India.

The annual average temperature of the surface water is approximately 88 degrees F (28 degrees C). The water temperature varies between 82 and 102 degrees F (25 and 35 degrees C) throughout the year. Several important and large rivers of India, Bangladesh, and Myanmar flow into the bay. The GANGES, Brahmaputra, and Meghna drain into the bay from the north. Mahanadi, Godavari, Krishna, and Cauvery, the Indian rivers, feed it from the west. The IRRRAWADDY RIVER of Myanmar flows into it from the east. "The rivers of Bangladesh [mainly the Ganges, Brahmaputra, and Meghna system] discharge the vast amount 1,222 million cubic meters of fresh water (excluding evaporation, deep percolation losses and evapotranspiration) into the bay" explains a Bangladeshi reference.

A constant addition of fresh water from the surrounding rivers essentially affects chemical and physical properties of the water of the Bay of Bengal. Owing to the dilution, river mouths have a very low salinity (1 to 5 percent) as compared to open water (32 to 34.5 percent). Salinity decreases away from the coast to the open water. It also varies with the season. Discharge of fresh water from the rivers adds nutrients to the bay, predominantly along the coastal belt, thus turning it into an important fishing ground. Important species are varieties of shrimp, flounder, and snapper. Overfishing is leading to depletion of the resource. The coastal reaches of the Bay of Bengal are being polluted continuously by oil traffic, effluent discharge, and chemicals used in agriculture. International cooperation is necessary to prevent such pollution.

Before the advent of steamships, the bay was used by fishermen, traders, and occasional conquerors using sail boats and monsoon winds that reversed directions during the summer and winter seasons. During the 16th and 17th centuries, Portuguese pirates operated in the bay, but later it was widely used by British and French colonizers. Using the bay, the British colonized all the countries adjacent to it except Thailand, thus turning it into a British lake. Three major ports used by the British were Calcutta, Madras, and Rangoon.

## Beijing

BEIJING IS LOCATED in the northern part of the North China Plain, about 100 mi (160 km) northwest of the Bohai Sea. As capital of the People's Republic of CHINA, Beijing is the core of a special municipal district, giving the region political status equivalent to that of an entire province. For this reason, the city's area (6,489 square mi or 16,808 square km) is much greater than one might expect.

At the core of this "municipality" is the Beijing metropolitan area, which is surrounded by mountains on the west, north, and northeast, with flat plains extending to the south and southeast. Most of the remaining area beyond the metropolitan core is mountainous, with elevations ranging from 3,280 to 4,920 ft (1,000 to 1,500 m) above sea level. The city's highest point is 7,554 ft (2,303 meters) above sea level. Beijing has short springs; hot, humid summers; short, sunny autumns; and cold dry winters with 200 or so frost-free days annually. While the winters are long and cold, Beijing doesn't get much snow.

Because of the city's unique geography, with mountains to the west, north, and northeast, and onshore monsoon airflows, the weather is often punctuated by severe dust storms driven by very large high-pressure centers that form over northwestern China's deserts. Annual rainfall has been relatively low recently (14 in

or 36 cm in 2002), but the long-term average is around 16 to 18 in (41 to 46 cm) per year, making the area suitable for agriculture.

Historically, the Yongding, Chaobai, and Juma rivers have provided important water resources as they flow through mountains and southeastern plains toward the Bohai Sea. In addition to the three rivers, the city has relied heavily on waters from three major reservoirs located in the shelter of the surrounding mountains. But unlike the city's early years under the Yuan Dynasty, Beijing's major limitation today is water.

As the urban area expands in both size and population, increasing pressure is being put on the region's water resources, particularly groundwater resources. And because the surrounding lands provide most of the basic fruit and vegetable needs for the local population, farmers have had to resort to increased irrigation practices to maintain production levels. At the same time, the tremendous demand for land for industrial, commercial, and residential purposes, and the resulting expansion of the city proper, is leaving less and less land available for local agriculture and increasing the city's reliance on outside sources of food production. This increasing need for water from all sectors has led to increased use of groundwater stored in the aquifers beneath the city. But this use has a tremendous cost, particularly from a sustainability standpoint, if not managed properly.

Evidence from the archaeological record suggests that the lands now occupied by Beijing have experienced human presence for a very long time (dating back some 500,000 years to "Peking Man"). In these early years preceding the Yuan Dynasty (13th century), the area's geography was much different than what we see today, containing a rich and diverse wetland environment with numerous rivers, streams, and swamps. This rich wetland environment—with lush grasslands around its edges, surrounding mountains, and easy access to the high Mongolian Steppe and traditional homelands—was a factor for the Mongols in locating their capital (Dadu) at what is today Beijing.

Although serving off and on as China's capital beginning with the Liao Dynasty in 927, it is under the Mongols and their Yuan Dynasty that the city began taking on its present character. The Mongols undertook major ecological engineering projects, expanding and reconstructing the city's inner and outer walls, creating parks and gardens, and developing drainage projects to create local canals and waterways. It is also under the Mongols that the Grand Canal was extended

to the north, creating a vital food and communication link between Beijing and the heavily populated agricultural lands in the lower and middle Yangtze Basin to the south.

Beijing has served off and on as China's capital beginning in 927 with the Liao Dynasty, extending through the Jin, Yuan, and Ming dynasties until the end of the Qing Dynasty in 1911. After the overthrow of the Qing Dynasty in 1911, Beijing passed into the hands of various warlords until 1928, when it once again became the capital of China under the Nationalists (Guomindang).

Between 1937 and 1945, the Japanese occupied Beijing following their invasion of China. With the founding of People's Republic of China in October 1949, Beijing was once again designated as the capital, continuing its stature as the political and cultural center of China. However, when the communists established their rule in 1949, the government brought in more heavy industry (steelworks, textile factories, and machine factories) in an effort to make the city an industrial center as well.

The communists sought to make Beijing self-sufficient by expanding its territory to include outlying rural counties. After 1978, when the first economic liberalizations began, Beijing became a center of finance

*The Forbidden City, now a museum in Beijing, was the secretive political capital of China for centuries.*

as well. In the period following the reforms introduced by Deng Xiaoping in the late 1980s and early 1990s, Beijing's economic character has continued to grow and change. Today the interest is moving toward more high-tech industries with suburban office parks. There is exceptional growth in the insurance, real estate, and health care sectors of the economy, all fueling China's growing middle-class population.

In addition to being a political and cultural center, Beijing also thrives as a center of international activity and tourism. Great changes have taken place since the founding of the People's Republic of China in 1949. The city walls that once dominated the landscape in what is today the central business district have been demolished to facilitate transportation and allow for the expansion of residential and business sectors. Plans for future development are to retain the symmetrical layout of the old city on its north-south axis, extending out into the suburban districts. The overall plan covers an area of about 386 square mi (1,000 square km), with a traffic network of five concentric beltways, 28 radial roads, and underground and suburban railways to further link the city center with outlying areas and surrounding towns. With Tiananmen Square at the center, offices along Chang'an Boulevard (the city's main east-west corridor) will concentrate on state, political and economic affairs. The areas around the Palace Museum (Imperial Palace or Forbidden City) and city gates as well as the lakes have been designated landmark districts. And with a look to the future, an increasing number of historical and cultural sites are being renovated as the city prepares to host the 2008 Olympics.

At the end of 2002, Beijing had a total population of 14.56 million residents, 11.49 million of whom were registered as permanent residents. The remaining 3 million people make up a floating workforce with official permission to stay in the city and work temporarily or attend one of the city's 37 universities, most of which are in the Haidian District. The city's population geography is diverse, with all 55 of the recognized ethnic minorities within the population. As with all world capitals, there is a large expatriate community (about 20,000 people) throughout the city's core, giving the more frequented areas near tourist attractions, government offices, shopping districts, and university settings an interesting cosmopolitan feeling. Beijing is filled with major historic attractions. Some of the more familiar sites in Beijing, such as the Forbidden City, the Great Wall, Peking Man Relics, the Temple of Heaven, the Summer Palace, and the Ming Tombs are World

Cultural and Natural Heritage sites approved by the United Nations.

## Belarus

**Map Page** 1132 **Area** 128,997 square mi (207,600 square km) **Population** 10,322,151 (2004) **Capital** Minsk **Highest Point** 1,135 ft (346 m) **Lowest Point** 295 ft (90 m) **GDP per capita** \$6,000 **Primary Natural Resources** forests, peat deposits, oil.

**BELARUS, FORMALLY BELORUSSIA**, also called White Russia, is bounded on the west by **POLAND**, on the northwest by **LATVIA** and **LITHUANIA**, on the north and east by **RUSSIA**, and on the south by **UKRAINE**. Ethnic Belarusians, who speak an East Slavic language closely related to Russian and Ukrainian, make up more than three-quarters of the population. Ethnic Russians are the largest minority group, followed distantly by Ukrainians and Poles.

Much of Belarus consists of flat lowlands separated by low hills and uplands. The highest point, Dzaryzhynskaya Hara, is only just over a thousand feet in elevation. Belarusian uplands were created during the last ice age. The limit of the last advance of the ice sheet lay across the country and is marked by a line of terminal moraines, known as the Belarusian ridge (Belaruskaya Grada).

This ridge runs west-southwest to east-northeast from the Polish frontier north of Brest toward Smalensk and consists of low, rolling hills. River valleys cut the ridge into a series of uplands, the sequence being: Hrodna upland, Vaukavysk upland, Schara valley, Navahradak upland, Nioman valley, Minsk upland, Biarezina valley, Dzvinia and Vitsebsk-Nieviel upland, Dnieper upland and a final group of uplands

along the eastern boundary. The highest group is the Minsk upland.

North and south of the ridge lie extensive lowlands. To the south lies the biggest Belarusian lowland called Paliessie, which is drained by the Prypiac River and its tributaries. The Prypiac River flows eastward to join the Dnieper River, which crosses the eastern part of Paliessie from north to south. In northern Belarus lie two more large lowlands: the Nioman lowland, drained by the river of that name, in the northwest, and the Polacak lowland, drained by the Western Dzvina, in the north. These two lowlands are separated by two morainic ridges, the Ashmiany and Svientsiany ridges, with the Viliya valley between them. The two northern basins contain many lakes of glacial origin, the largest of which is Lake Narach. Thus, Belarus falls into three main drainage basins, the Dnieper-Prypiac basin draining into the BLACK SEA, and the Nioman and Western Dzvina basins, draining into the Baltic Sea.

Forests cover about one-third of the country's area. The Belovezhskaya Forest, which straddles the Belarusian-Polish border, is home of the rare European bison, or wisent. The Pripet Marshes occupy much of southern Belarus. Belarus's continental climate is moderated by maritime influences from the ATLANTIC OCEAN and is characterized by cold winters, mild summers, and moderate rainfall. Much of the Belarus land is suited to crop production, especially fodder crops. Belarus is generally poor in mineral resources, but it does have sizable deposits of potassium salts at Soligorsk, south of Minsk, which provide potash fertilizer for export.

Belarus has clear evidence of early prehistoric settlement. Between the 6th and 8th centuries, Slavic tribes moved into the region, eventually forming local principalities that came under the sovereignty of Kievan Rus in the mid-9th century. The Mongols overthrew Kiev in 1240, and most of the Belarusian land passed to Lithuania, though Belarus retained substantial autonomy. Poland was united with Lithuania in 1386, and Belarus developed a largely Polish-speaking class of landowners. By the three divisions of Poland in the late-18th century, Russia acquired all of what became known under its rule as Belorussia.

From 1918 to 1921, Belorussia was fought over by the Germans, the Bolshevik government of Russia, and a reconstituted Poland, with the result that western Belorussia was yielded by the Bolsheviks to Poland. In the meantime, the Bolsheviks had in 1919 proclaimed a Belorussian Soviet Socialist Republic and in 1922 made it a part of Soviet Union. Finally, with the breakup of Soviet Union, the Belorussian republic gained inde-

pendence in July 1990, and changed its name to Belarus.

## Belgium

**Map Page** 1131 **Area** 11,790 square mi (30,510 square km) **Population** 10,289,088 **Capital** Brussels **Highest Point** Signal de Botrange 2,290 ft (694 m) **Lowest Point** 0 m **GDP per capita** \$29,000 **Primary Natural Resources** coal, natural gas.

ALTHOUGH IT OCCUPIES a central position at the economic crossroads of western Europe, and its people have been central in the development of European society for over a thousand years, Belgium as a state has existed only since the early 19th century. The Belgian people share much of their culture with their Dutch neighbors to the north but have been deeply affected by proximity to northern FRANCE and by important transportation links to GERMANY in the east. The result is a nation that is both divided between French and Germanic culture and language, and a model for interethnic cooperation that provides an ideal setting for institutions such as the NORTH ATLANTIC TREATY ORGANIZATION (NATO) and the EUROPEAN UNION (EU).

Belgium is one of the three countries known as the Low Countries, which occupy the northwestern edge of the North European Plain. As the name indicates, most of the territory of these countries—Belgium, the NETHERLANDS and LUXEMBOURG—is flat and close to sea level. Much of the area adjacent to Belgium's 40-mi

(66-km) North Sea coast is reclaimed land, protected from flooding by dikes and canals. The landscape becomes hillier in the central parts of Belgium and rises to low forested mountains in the southeast. This latter region is known as the Ardennes and is one of the largest areas of forest in western Europe. The Meuse River cuts its way through this wild part of the southeast, joined by its tributaries, the Sambre and the Ourthe, before passing into the Netherlands (as the Maas).

Further west, other large rivers cross Belgium, including the country's most important river, the Scheldet (Escaut in French), and its chief tributary, the Leie (Lys). But like the Meuse, the mouth of the Schelde is in the Netherlands, though the port city of Antwerp lies just a few kilometers inland. Antwerp is not only Belgium's most important port, it is the fourth-largest port in the world. Belgium's other port is Ostend, on the North Sea, connected to the Belgian interior via a series of canals. Other canals connect Antwerp to the Dutch ports of the lower Rhine, and the industrialized cities of the northwest to the mineral resources of the south and southeast.

The kingdom of Belgium is divided into 10 provinces: West Flanders, East Flanders, Antwerp, Flemish Brabant, Walloon Brabant, Hainaut, Namur, Limburg, Liège, and Luxembourg. Since 1993, it has also been divided into three regions—Flanders, the Brussels-Capital Region, and Wallonia—as well as three “communities,” one for each of the three official languages of the kingdom: Flemish, French, and German. These regions and communities roughly overlap but also have differences: The Brussels-Capital Region is an enclave within the Flemish-speaking region and is officially bilingual; the German-speaking population (less than 1 percent) live in several small towns close to the German border (the largest is Eupen). Flanders and Wallonia have roughly equal percentages of the land area, but Flanders has nearly twice as many people. This part of the country has one of the highest population densities in the world and includes some of Europe's most productive cities, including Bruges, Ghent and Antwerp. The French-speaking Walloon community is traditionally rural and less economically developed, resulting in some resentment that has threatened to break the country apart.

The unifying role of the monarchy and of the international position of Brussels as the “capital of Europe” goes a long way to ease this tension. As headquarters of NATO, the EU, and numerous other multinational corporations and organizations, Brussels has more resident foreigners (one in three), mostly diplomats and

journalists, than any other city in Europe. It is estimated that about 23,000 “Eurocrats” live in Brussels. Immigrants from North Africa and TURKEY also make up a sizable percentage of the population. In the past, Brussels has been a center for heavy industry, linked to the coalfields of Hainaut, Namur and Luxembourg, one of the areas first affected by Europe's INDUSTRIAL REVOLUTION in the early 19th century.

Cities such as Mons, Charleroi, and Liège were built on coal but have suffered greatly since the shift away from coal as a primary fossil fuel in the late-20th century. The steel industry in this area is also being shut down, further accentuating the economic disparities between the French-speaking south and the successful economic engines of the Flemish-speaking north.

Flanders has long been a center of industry and prosperity; the soil in this area is sandy and relatively unproductive, so the local inhabitants turned to trade and manufacturing. Bruges lace and Ghent woolen cloth were famous as early as the 14th century.

Today, this region is a leader in biotechnology and petrochemicals, but also continues more traditional trade in textiles and diamonds (Antwerp is the diamond trading capital of the world). Wallonia is now being developed as a center for agricultural innovations. Traditional specialties from all across Belgium include over 350 varieties of beer and rich chocolates.

## Belize

**Map Page** 1136 **Area** 8,865 square mi (22,966 square km) **Population** 266,440 **Capital** Belmopan **Highest Point** 3,805 ft (1,160 m) **Lowest Point** 0 m **GDP per capita** \$4,900 **Primary Natural Resources** bananas, cocoa, citrus, sugar, fish.

BELIZE (“BELICE” IN SPANISH), formerly the Settlement of Belize in the Bay of Honduras (prior to 1862), British Honduras (1862–1973), and Belize thereafter, became independent on September 21, 1981.

Located on the Caribbean coast of northern Central America, it shares a northwestern border with the Mexican state of Quintana Roo, on the west with the Guatemalan department of Petén, and on the south with the Guatemalan department of Izabal. Honduras lies 46 mi (75 km) away at the two nations’ closest point across the Gulf of Honduras and CARIBBEAN SEA to the east. The current name is derived from the Belize River (also called the Old River) and Belize City, the country’s largest city, principal port, and former capital.

### BARRIER REEF

The eastern border has numerous marshy lagoons flanked by the world’s second-longest barrier reef (240 mi or 386 km). The nation is shaped like a rectangle extending 174 mi (280 km) north-south and about 62 mi (100 km) east-west, with a total land boundary length of 321 mi (516 km); the border with GUATEMALA is 165 mi (266 km) and with MEXICO 155 mi (250 km). Cay islands include about 266 square mi (690 square km), and the Hondo and the Sarstoon rivers define most of the northern and southern boundaries. The western border follows no natural features but runs north-south through lowland forest and highland plateau. The entire area of the country is slightly larger than EL SALVADOR or MASSACHUSETTS.

Geologically, Belize is divided into two primary physiographic regions, the Maya Mountains rising to 3,675 ft (1,120 m) and northern lowlands drained by 18 major rivers and streams. Most of Belize lies outside the tectonically active zone that underlies most of Central America. The climate is subtropical.

### POLITICS AND POPULATION

Belize was under the political control of a series of Maya city-states prior to the arrival of English colonists in the early 1600s. A 200-year territorial conflict between Britain and SPAIN became a conflict between Belize and Guatemala, from the independence of Spanish colonies into the 1990s. Modern Belize consists of six political districts (Belize, Cayo, Corozal, Orange Walk, Stann Creek, and Toledo); the new capital, Belmopan, is centrally located in the interior.

The country has a population that is fragmented into many racial and cultural groups. The two largest groups are Creoles; English-speaking or Creole-speak-

ing blacks and people of mixed African and European heritage, and Mestizos, Spanish-speaking people of mixed Mayan and Spanish European heritage. In addition there are Garifuna (Afro-Caribs originally from the Lesser Antilles), Maya (descendants of the original inhabitants), East Indians, Chinese, Arabs, and Europeans. English is the official language, but a local English dialect, Belizean Creole, is spoken by most groups; Spanish is widely spoken outside of Belize City. Other languages include Mayan dialects (Yucatecan, Mopán, and Kekchí), Garifuna, and Low German. Most Belizans are Roman Catholic, but there are significant Protestant minorities.

## Benares

BENARES (also Banâras, Varanasi) is an ancient city in the state of Uttar Pradesh, in northern INDIA. Its population is just over 1 million (1991). Although the name *Benares* appears on many maps, it is actually a corruption of the official Indian name of the city, Varanasi. In addition to many religious institutions and festivals, the city is home to Banâras Hindu University, a major center of Sanskrit studies.

Hindus also call Benares the City of Light (Kâshî), as in “enlightenment,” because of its close association with the development of Indian spiritual life, a role it continues to play. There are approximately 1,500 Hindu temples and other religious buildings within the city limits. Its very location, on the western bank of a curve in the GANGES RIVER (Gangâ), is sacred in the minds of many Indians.

The basic geography of the city, with hundreds of temples and buildings crowding the western bank of the Ganges, facing an uninhabited floodplain on the eastern bank across the river, represents transcendence of this life to the “far shore” (the next life) to many believers. About a million believers a year make pilgrimages to the city of Benares, especially during annual

festivals. Most descend long stone steps (ghats) to immerse themselves in the holy waters of the Ganges.

The city is also a final destination for Hindus who hope to obtain salvation from the cycle of birth and death by dying in this sacred city. Although close association with death is usually regarded as inauspicious or even polluting in Indian society, because of the holy status of Benares, the regions of the city where bodies of the dead are cremated are especially revered.

Many Indians also bring the ashes of their dead relatives to Benares, where they are dispatched to the next world in the river's waters. City officials have recently supplemented the traditional wood-burning funeral pyres of the cremation grounds at Manikarnikâ downriver of the city with an electric crematorium at the Harishchandra Ghât, in an effort to reduce air pollution.

Though it has never been a seat of political authority, Benares is one of the oldest Indian cities, dating back at least 2,500 years, and has long been a site of Hindu worship. Other religions are also represented in the history of the city. It was at Deer Park just outside Benares where the Buddha made his first sermon (circa 528 B.C.E.). There have been many Muslims who lived and worshiped in Benares as well, and the mosque of the 17th-century Mughal Emperor Aurangzeb is found at the highest spot of the city.

Western visitors to India have been alternately fascinated and repelled by Benares for centuries. The city seemed to many Western visitors to encapsulate the exotic and sublime appeal of the East, with its mystical mood and myriad spiritual practices. On the other hand, the masses of humanity bathing in the polluted (if spiritually purifying) waters of the Ganges, as well as the worship of all manner of icons, shocked and offended other Western visitors.

## Benelux

BENELUX IS THE name of the customs union created in 1956, named for the initial syllables of its three member states: BELGIUM, NETHERLANDS, and LUXEMBOURG. The name originally applied to the economic pact between the three countries, the Benelux Economic Union, but is now also used to refer to the three countries as a geopolitical entity. The goal of the customs union was to help rebuild the economies of the Low Countries after the devastation of World War II through the promotion of free movement of workers, capital, services, and goods between all three member states. The Benelux commission, with its headquarters based in Brussels, set about removing all barriers to free trade such as border tariffs and work permits.

The idea of a unified Low Countries is not new to the 20th century. In the Middle Ages, the entire region formed a collective economic unit under the Valois Dukes of Burgundy and their successors after 1477, the Hapsburgs. The 17 provinces of the Low Countries, plus the Duchy of Luxembourg, subsequently formed an essential part of the empire of Hapsburg Spain, the processing plant for boatloads of silver arriving each year from the New World.

Major cities like Ghent, Bruges, and Antwerp created industries and banking empires that rivaled northern Italy for the lead in the technological and economic revolution of the Renaissance. The breakup began with the revolt of the Dutch in the late 16th century. Their golden age in the 17th century was had mostly at the expense of their southern neighbors, who continued to be ruled by SPAIN, and then AUSTRIA until the 1790s. The three states were united once again at the end of the Napoleonic Wars, under the single rule of the Dutch, but this union lasted only 15 years, and the Belgians revolted against Dutch rule in 1830. A truncated Luxembourg remained attached to the Netherlands, however, until 1890, when it too became completely independent. Each maintained a strict policy of neutrality toward their larger neighbors.

The devastation of the two world wars, however, convinced the three states that going it alone would never secure the prosperity of all three countries. They had few raw materials, but abundant skilled labor, and easy access to the sea and major shipping lanes: Rotterdam and Antwerp are the largest and most active ports in Europe. Relatively small populations and highly productive industries meant all three were dependent on trade and international cooperation, stability, and peace. The impetus for their cooperation was the im-

portance of getting coal and steel from the hills of southern Belgium and Luxembourg, to the factories and ports of the Belgian and Dutch coasts as smoothly and efficiently as possible. A plan for the Benelux Economic Union was therefore formed by the governments of these countries before World War II was even over.

From their exile in LONDON, England (all three countries were under Nazi occupation), representatives of the three governments laid down the basic plan for the union in 1944, but it was not put into place until the formal signature of the Union Treaty at the Hague in 1958, by which time a larger group, inspired by the same principles, had also been created, the ECSC (European Coal and Steel Community), formed in 1952 by the three Benelux nations, plus West Germany, FRANCE, and ITALY.

This led to the formation of the European Economic Community in 1957, which evolved into the EUROPEAN UNION (EU) in 1993. The Benelux Customs Union served as a model for the creation of the EU, and many of its treaties and laws are simply extensions of Benelux policies. The Benelux nations were also founding nations of the NORTH ATLANTIC TREATY ORGANIZATION (NATO) in 1949, giving up their neutrality for stronger alliances with their larger neighbors.

Relations between the Benelux countries led to increased laxity in border crossings, eventually developing into the Schengen agreement of 1985, signed in the small town of Schengen, Luxembourg. This agreement removed most travel barriers for its original signatory nations, the Benelux countries, France, West Germany, Spain, and PORTUGAL, and now including additional EU members. One of the primary goals of the Benelux union was to pursue the development of Europe, and it continues to take common initiatives to stimulate integration.

Although the economic necessity for the union has mostly dissipated (coal and steel are no longer the power they were), the partnership is still useful, allowing these small states to coordinate their points of view so as to have the same weight as the larger, more populous nations of the EU.

**BIBLIOGRAPHY.** *Encyclopedia Americana* (Grolier, 1997); Wayne C. Thompson, *Western Europe 2003*, The World Today Series (Stryker-Post Publications, 2003); "Benelux," [www.benelux.be](http://www.benelux.be) (August 2004); *Planet Earth World Atlas* (Macmillan, 1998).

## Benguela Current

THE BENGUELA CURRENT is one of the world's four major eastern boundary currents. It flows northward off the coast of southwestern Africa along the western coasts of SOUTH AFRICA, NAMIBIA, and southern ANGOLA. The Benguela Current, along with the South Equatorial Current, and the northern part of the Antarctic Circumpolar Current make up the South Atlantic subtropical gyre. The Benguela Current draws icy-cold waters from the Southern Ocean and carries them northward along the coast of Africa. Because of these cold waters, rain clouds do not develop over the southwest coast of Africa, contributing to the parched climate of the KALAHARI and Namib deserts.

The Benguela Current is one of those regions off the west coasts of the continents where there is an upwelling of cool, nutrient-rich water due to the coastal edge of the continental shelf, the prevailing winds, and the Earth's rotation. Because of these nutrient-rich waters, there is a huge abundance of marine life of all kinds. This has resulted in a large and plentiful fishing industry off Africa's southwest coast. In direct contrast to this, there are areas of the Benguela Current off the coast of Namibia and along the Walvis Ridge in which there are no fish to be found. This is due to a buildup of harmful algae blooms and high hydrogen sulfide gas levels in the water that are toxic to marine life. This phenomenon is known as "red tide" and is usually confined to localized inshore areas, such as off the west coast of FLORIDA. But because of changes in wind direction, it can occur offshore in the Benguela Current.

About 93 to 124 mi (150 to 200 km) off the coast of South Africa, the Benguela Current begins with an upwelling of ocean currents. It spans from this area around 35 degrees south northward to between 14 degrees and 17 degrees south, where it meets the Angolan Current. At this northern boundary, the change is more dramatic, with cold and warm water meeting to form a thermal front along the coast. The Benguela Current covers around 57,915 square mi (150,000 square km) when using the continental shelf as the offshore boundary line.

The continental shelf near the Benguela is from 40 to 80 mi (64 to 128 km) wide. From the shelf, the ocean bottom slopes steeply away into the abyssal depths of the Cape and Angola basins, each about 16,400 ft (5,000 m) deep. These BASINS are separated by the Walvis Ridge, which starts just off the coast at about 20 degrees south and stretches to the west, linking up with the central Atlantic Ridge. The Walvis

Ridge rises to above 2,460 ft (750 m) in many places along its track. This area is exposed to persistent along-shore winds associated with a high-pressure weather system.

The surface temperatures of the Benguela Current are about 14 degrees F (8 degrees C) colder than average for coastlines in these latitudes. The coldest waters of the current run right along the coast of Africa, with very little seasonal variation except in the extreme south near Cape Town, South Africa, where the water is colder in the summer than it is in the winter. Surface temperatures average about 50 to 59 degrees F (10 to 15 degrees C) near the coast and reach up to 77 degrees F (25 degrees C) on the surface, out along the continental shelf.

## Benin

**Map Page** 1113 **Area** 43,483 square mi (112,620 square km) **Population** 7,041,490 **Capital** Porto-Novo **Highest Point** 2,158 ft (658 m) **Lowest Point** 0 m **GDP per capita** \$1,100 (2003) **Primary Natural Resources** oil, limestone, marble, timber.

BENIN IS LOCATED in West Africa and is bordered to the west by TOGO, to the north by NIGER and BURKINA FASO and to the east by NIGERIA. It stretches 435 mi (700 km) from the NIGER RIVER to the Gulf of Guinea. Behind the southern coastal zone, there are a series of interconnected lagoons and lakes. Behind this coastal region is found an area of fertile clay soils that is generally flat, crossed by the wide marsh, through

which flows the Ouémé River. Northwest Benin is a region of forested mountains (the Atacora, highest point 2,150 ft or 655 m), from which the Mekrou and Pendjari rivers flow northeast to the Niger River (which is part of the country's northern border). The northeast is a highland region containing little fertile soil and covered mostly with savanna.

### POPULATION GROUPS

There are 42 ethnic groups in Benin, but its population is divided into four main ethnolinguistic groups: the Fon (in the south), the Yoruba (in the southeast near Nigeria), the Voltaic (in central and north Benin) and the Fulani (in the north). The country's official language is French. Almost three-quarters of the population follows traditional religious beliefs. Voodoo originated in Benin almost 350 years ago but was officially recognized only in 1996. About 15 percent of the Benin population is Muslim (mostly living in the north) and an equal number is Christian.

Benin's population is concentrated in the south and in rural areas. Most of the people engage in subsistence farming, with the main crops being cotton, corn, sorghum, cassava, beans, rice, peanuts, and palm oil. There is also an extensive freshwater fishing industry and a smaller sea fishing industry. Benin produces few manufactured goods, of which the largest are either processed agricultural goods (foods and beverages) or basic consumer items (textiles, footwear, ginned cotton). In 2002 the contribution of the agricultural sector to gross domestic product was 38 percent, while that of the industry was 15 percent and that of the service sector 47 percent.

Petroleum was discovered offshore of Porto-Novo in 1968, and in the 1990s was Benin's largest export. The other mineral resources found in the country (such as titanium, low-quality iron ore, ilmenite, and chromite) have not yet been extensively exploited. Apart from crude oil, the main exports are cotton, palm oil products, coffee and cocoa beans. The economy has been growing an average of 5 percent annually in the period 1991 to 2004, but rapid population growth has offset much of this increase. In 2001, 37 percent of the population was earning an income below the poverty line.

FRANKLIN COLLEGE, SWITZERLAND

## Bermuda

BERMUDA IS A UNITED KINGDOM overseas territory located 700 miles southeast of NEW YORK CITY in the North ATLANTIC OCEAN. With an area of 36.2 square mi (53.3 square km), the island colony has a population of 64,482 (2003). Bermuda is a primary tourism destination for East Coast Americans, and its capital, Hamilton, serves as a harbor for numerous cruise ships.

In 1506, a Spanish sea captain, Juan de Bermúdez, came upon uninhabited islands in the middle of the Atlantic Ocean and named them Bermuda. Although Bermúdez did not claim the land for SPAIN, the islands did become an important landmark for seafarers crossing the ocean from Spain to the New World. In 1609, an English admiral, Sir George Somers, was sailing from England to the new British settlement, Jamestown, VIRGINIA, in the New World. He landed in Bermuda and built replacement ships. Two men were left behind and claimed the land for Britain.

The British Jamestown Company soon became interested in the islands and three years later brought over 60 settlers to organize a settlement. Tobacco, cedar, whaling, and salt were vital to the early Bermudan economy. As the years passed, cedar forests were cleared for areas of land capable of cultivating potatoes, cabbages, onions, and tobacco.

Slaves were transported to the islands in 1616, and in 1684, Bermuda became a British colony. During the American Revolution, the Bermudan citizens remained loyal to the British, and in the War of 1812, the British navy used Bermuda as a base. The Royal Naval Dockyard on the western end of the island proved vital in maintaining British superiority in the North Atlantic. In 1834, slavery was abolished and around 5,000 slaves were freed. During the Civil War, Bermuda became a center for southern blockade-runner ships, which would attempt to break the Union naval blockade.

In 1874, the government of Bermuda and the Quebec Steamship Company agreed on a contract that created steamship service between NEW YORK CITY and

*Bermuda, a British dependency, is a tourist mecca for vacationers from the United States, especially those arriving via cruise ship.*

Bermuda. Bermuda was becoming a popular vacation destination for many people, including the famous American author Mark Twain, and the tourism industry expanded.

In 1937, Darell's Island Marine Airport was opened and air travel began to and from Bermuda. Six years earlier, a railroad was built in the territory. When World War II began, the strategic location of the islands proved vital. Part of the lend-lease agreement between Britain and the United States resulted in a portion of Bermuda being handed over to the American military. After World War II, women were allowed to vote and black voters were given greater freedom. A constitution was signed in 1968, which allowed for full self-government but left security and diplomatic affairs to the British.

The territory was affected by race riots throughout the 1970s, but in the 1980s, the construction industry prospered. Construction resulted in an incredible expansion and employment grew 34 percent. However, the economy faltered in the 1990s and many Bermudans called for full independence from Britain. In 1995, after only 58 percent of the electorate voted, a referendum failed to gain enough votes for independence. That same year, the naval bases occupied by the American military since World War II were handed back to the Bermudan government.

By 1998, the Progressive Labor Party's Jennifer Smith, was selected as the premier. She became the first woman and the youngest person to hold the post. In 2003, Alex Scott became premier. Bermuda is prospering economically and continues to attract a multitude of international companies and holiday seekers.

## Bhutan

**Map Page** 1123 **Area** 29,204 square mi (47,000 square km) **Population** 2,139,549 (2004) **Capital** Thimphu **Highest Point** 24,780 ft (7,553 m) **Lowest Point** 318 ft (97 m) **GDP per capita** \$1,300 **Primary Natural Resources** hydropower.

BHUTAN IS A LANDLOCKED country located in the eastern part of the HIMALAYAN MOUNTAINS, bordered by INDIA in the south, east, and west and by TIBET in the north. At its lowest east-west corridor, Bhutan stretches around 186 mi (300 km), and it measures approximately 105 mi (170 km) at its north-south direction.

There are three main ethnic groups in Bhutan. The Ngalungs or Ngalops (often called Drukpas) live in the northwestern part of the country. They speak Dzonkha and are called Drukpas as they follow the Drukpa Kargyupa school of Tibetan Buddhism. The second ethnic group is called Sharchops and they inhabit the eastern and central region and practice Nyingmapa, a branch of Mahayana Buddhism. The Sharchops speak Tsangla, Kheng, Kurteop, Sharchopkha, and Brokpa dialects. The third major ethnic group is called Lhotshampas and they live in the southern foothills of Bhutan and speak primarily a Nepali language.

Bhutan is ruled by a hereditary monarch who governs the country with the support of a national assembly and the council of ministers. Bhutan does not have

any written constitution. In 2001, the Bhutanese king commissioned the drafting of a constitution, which is to become effective in 2005. The royal government of Bhutan is guided by the aid and advice of the government of India in regard to its external relations. India is responsible for defense and foreign relations as per Article 2 of the Indo-Bhutan treaty.

Bhutan is primarily an agricultural country. The traditional form of agriculture is the main subsistence occupation for the majority of Bhutanese people, who involve themselves with agriculture, livestock, and related activities. The hydroelectricity power sector provides the single biggest revenue to Bhutan. India has been the prime market for Bhutan's finished products and imports. Bhutan imports from India necessary household items such as rice, vegetables, poultry, fish, wheat, and salt. Bhutan also imports other items such as petroleum products, automobiles, steel, sugar, medicines, and textile goods.

Bhutan has been identified as one of the 10 biodiversity hot spots in the world and as one of the 221 global bird areas. Its ecosystems harbor some of the most endangered species of the Himalayas, with an estimated 770 species of birds and over 50 species of rhododendron. They are enriched by a rich a wildlife with animals such as the snow leopard, golden langur, blue sheep, water buffalo, tiger, and elephant.

## Bight of Benin

A "BIGHT" REFERS TO a bend or curve, most often a crescent shape, that forms an open bay in a coastline. The Bight of Benin is a roughly 500-mi- (800-km-) long bend in the West African coast, stretching from near the mouth of the Volta River (Cape Saint Paul) in GHANA eastward across the coastlines of TOGO and BENIN to the DELTA of the Niger River in NIGERIA. The Bight of Benin received its name from the centuries-old kingdom of Benin located in southern Nigeria. The na-

tion of BENIN (formerly Dahomey) consequently received its name from the coastline in 1975.

The Bight of Benin is a region rich in culture and history. Prior to European colonization, major African kingdoms existed in the area, including the Asante (1750 to late 1800s) in what is now Ghana, Fon (1700s) and Dahomey kingdoms (1800s) in what is now Togo and Benin, and the Yoruba (1000s to 1800s) and Benin (1200s to 1897) kingdoms in what is now Nigeria.

Portuguese explorers, reaching the area in 1485, found the city of Benin to be as well organized as cities in Europe. Between 1500 and 1800, the Benin kingdom expanded power, largely through trade with the Portuguese. The tropical climate brought hardship to Europeans from disease and trying conditions. An old rhyme stated, "Beware, beware the Bight of Benin, for few come out though many go in."

Also known as the Slave Coast, the region was an important area of slave trading from the 1500s to the 1800s. Some pre-European slavery was practiced, largely as prisoner labor resulting from wars among kingdoms. Slavery expanded with European contact, with mostly males sent abroad and females staying within Africa. The Dahomey kingdom became a major source of transatlantic slave trade to BRAZIL, the Caribbean, and the UNITED STATES. The kingdom was the origin of an estimated 14.5 percent of U.S. slaves. The cities of Abomey and Ouidah became international cultural and trading centers.

Many slaves spoke the Gbe language and practiced the religion of Vodun (a predecessor of Haitian voodoo). As many as 10,000 to 15,000 slaves were exported per year. By the early to mid-1700s, so many local slaves were exported that prices rose and other African regions to the west and south were exploited. King Duezo of Dahomey brought independence from the Yoruba in the early 1800s. Abolition of slavery in Brazil in 1880 brought liberated slaves back from Brazil. Many were skilled tradesmen who formed an upper class in Porto Novo and Lagos, bringing some Portuguese architecture that had been popular in colonial Brazil.

Palm oil then became the major regional export until petroleum oil was discovered in the Niger River delta in the 1950s. Cotton and cocoa are also major exports. The coastal population today includes the nations of Ghana (former British colony, 20 million), Togo (former German and French colony, 5 million), Benin (former French colony, 7 million), and Nigeria (former British colony, 130 million).

The Bight of Benin has a long dry season from November to the end of March, driven by northerly Harmattan winds. It has a first rainy season from April to July, a short dry period in August, and a second rainy season in September and October. Rainfall can exceed 10 in (25 cm) in June and 50 in (127 cm) annually. Average temperatures range from lows of 75 degrees F (23 degrees C) to highs of 85 degrees F (28 degrees C) in the wet season and 90 degrees F (32 degrees C) in the dry season.

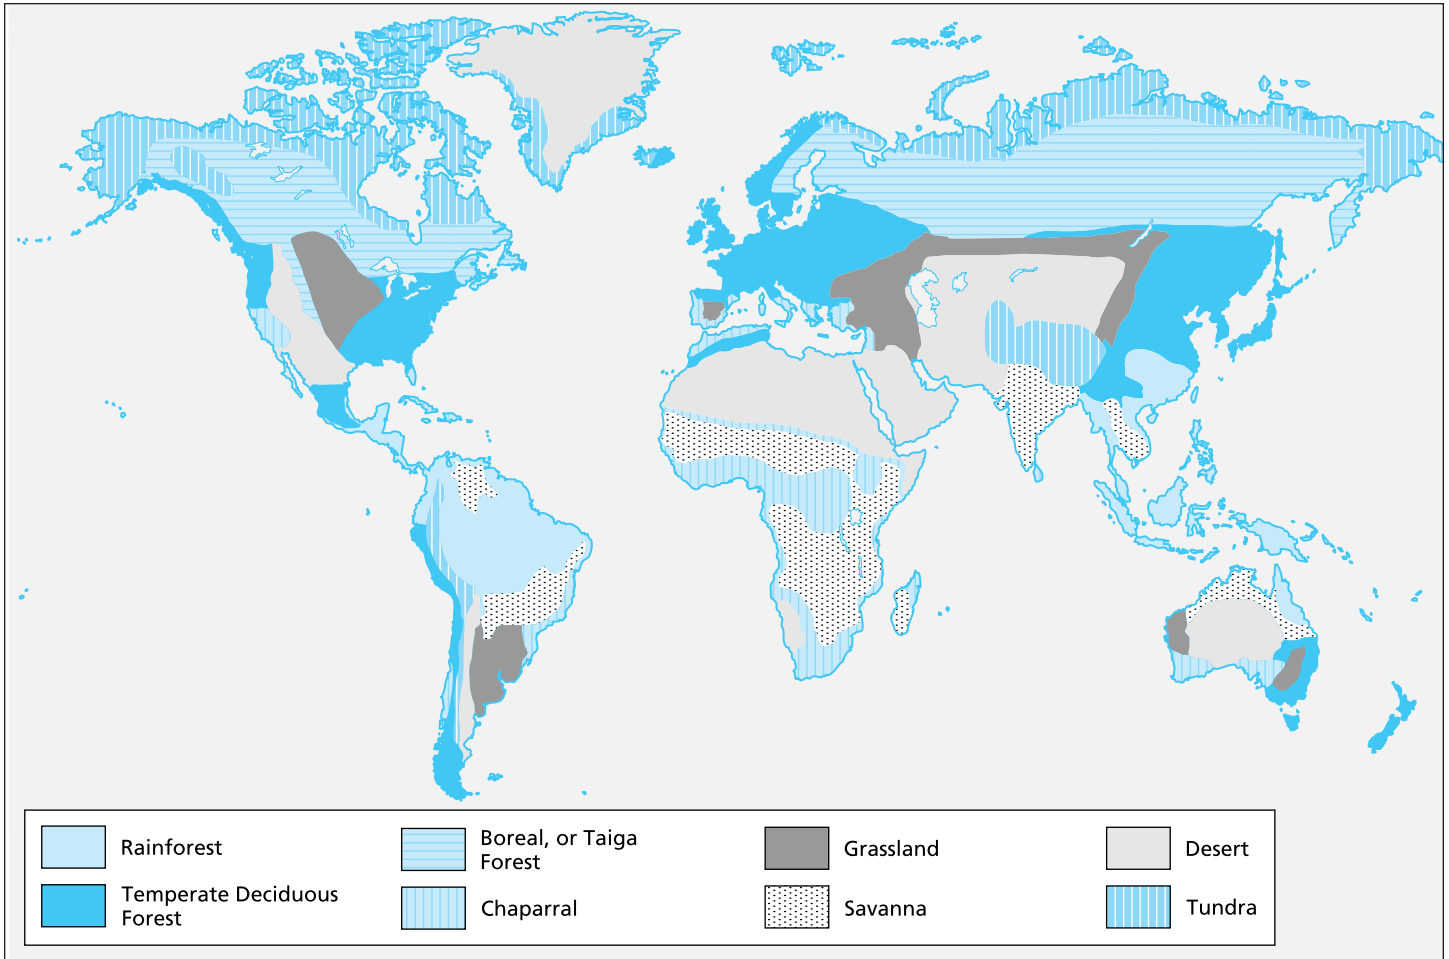

Major ports include Lomé (Togo), Cotonou (Benin), and Lagos (Nigeria). Ouidah was the only port in Benin until 1908. Ouidah today features a voodoo museum, the Sacred Forest, and Route of the Slaves, a short road with landmarks, statues, and villages along the route slaves took to the ships. North of Cotonou is Ganvié, a town of bamboo huts built on stilts for protection. Religious custom prevented Fon and Dahomey warriors from crossing into water. Much of the Bight of Benin coastline has white sand beaches, clear water, tidal flats, and coastal lagoons, accompanied by strong tides and currents.

## biome

A BIOME IS A classification of large areas of plant formations. The world's vegetation communities can be described in many ways depending on scale and controlling factors. The early plant geographers, notably F. E. Clements and V. E. Shelford, working in the UNITED KINGDOM and the UNITED STATES in the early 20th century, defined and classified the major plant formations with their associated fauna as biomes. Within each biome, there is a uniform life form of vegetation, for

*The biomes contain a wealth of natural resources that have sustained humankind and allowed the species to proliferate, but at a cost. Many human activities are contributing to ecosystem loss and species extinction.*

example, FORESTS and GRASSLANDS in which trees and grasses predominate respectively. All biomes are extensive and characterize large areas of the Earth's surface. Further subdivisions are possible; for example forests can be divided into coniferous, temperate, and tropical, and grasslands may be temperate or tropical. These subdivisions are usually linked with the prevailing climate because the annual temperature and precipitation regimes are important determinants of vegetation life form and species composition, which, in turn, influence animal communities. Thus, in traditional terms biomes are climatic climax communities, that is, they comprise plant and animal communities that have developed an equilibrium with their environment which facilitates definition as a unit.

There are rarely sharp boundaries between biomes but rather a gradation in a transition zone, similar to an ecotone, or boundary between ECOSYSTEMS, which can also be synonymous with biomes at the global

scale. The major biomes recognized on the Earth's land surface include the following:

1) TUNDRA: High latitudes, no trees, dwarf shrubs, herbs, grasses.

2) Forests: Taiga (coniferous forest) in high latitudes, evergreen tree species predominate; temperate forest: temperate latitudes/high latitude maritime, broadleaf species; temperate RAINFOREST: same as temperate forests above, especially Southern Hemisphere island locations, evergreen and broadleaf species; tropical forest: tropical latitudes with high rainfall, varied composition with evergreen and broadleaf species.

3) Savanna: Various types depending on tree/grass distribution, tropical latitudes with seasonal rainfall, grasslands to open forests.

4) Mediterranean-type: Sometimes described as chaparral, various types in areas of hot, dry summers and warm, wet winters, between temperate and tropical latitudes; mixed woodland, grassland, shrubs.

5) Grasslands: Various types, mid-latitude continental interior with a wide annual temperature range, grass species predominate.

6) DESERT: Highly variable, depending on precipitation volume and distribution, low latitudes with low rainfall, few trees and shrubs, ephemeral herbs and grasses, includes succulents.

Aquatic environments can also be classified into biomes, notably wetlands, freshwater environments, and marine ecosystems. The first two categories can be further subdivided depending on characteristics such as climate, acidity, alkalinity, and salinity. Marine ecosystems can be subdivided into two units: the LITTORAL or shoreline zone and the oceanic or open water zone. Examples of littoral ecosystems include mangrove swamps and salt marshes. The oceanic zone also varies roughly on a latitudinal basis reflecting water temperature and, hence, the prevailing climate.

An alternative classification can be applied to the vertical distribution of marine organisms, namely, the illuminated or photic zone near the surface, where light allows photosynthesis to take place; the nectonic zone, in which fish and aquatic mammals live; and the ocean floor, which may be rock, sand, or mud, where bottom-dwelling organisms (benthos) live.

The distribution and composition of biomes are not constant in geological time. Throughout the 5,000 million years of Earth history, changes in climate and earth movements have altered the configuration of the continents and the oceans. Evolution has given rise to new life forms. The most geologically recent alterations to the world's biomes occurred during the last 3 million years, the last Ice Age, when a series of cold periods (glacial stages) separated by warm (interglacial stages) began.

As temperatures waxed and waned, the world's biomes changed in extent and in composition. The biomes described above came into existence between 10,000 and 5,000 years ago during the current interglacial stage. The present biomes have also been substantially modified by human activity for which there is no precedent in earlier geological periods. The biomes contain a wealth of natural resources that have sustained humankind and allowed the species to proliferate, but at a cost. Agriculture, mining, logging, pollution, urban spread, tourism, and water extraction are all contributing to ecosystem loss and species extinction.

This alteration is also impairing the capacity of the biomes to provide essential services such as the circulation of elements and compounds between the atmos-

phere, vegetation, and soils, as in the carbon and nitrogen cycles. This is related to the regulation of climate as vegetation, especially trees, provide a huge store of carbon. But as deforestation occurs, increasing volumes of carbon enter the atmosphere as carbon dioxide and so exacerbate the problem of global warming caused by fossil-fuel consumption.

## bioreserve

BIOREServes, also known as BIOSPHERE reserves, are an internationally recognized type of conservation reserve. In 1970, the 16th General Conference of UNESCO (part of the United Nations), acting on the recommendations of the conference, launched the long-term intergovernmental and interdisciplinary program known as Man and the Biosphere (MAB). Crucial for the program was a project for the conservation of natural areas and of the genetic material they contain, which included the development of a coordinated worldwide network of protected areas, linked by international understanding on purposes, and standards, and exchange of scientific information.

These include biosphere reserves that contained representative land and coastal areas of each of the major or otherwise relevant ECOSYSTEMS within a nation's boundaries. The biospheres could be used as basic logistical resources for research, as areas for education and training, and as essential components for the study of many projects under the overall program, including a role of benchmarks or standards for measurement of long-term changes in the biosphere as a whole.

In the design of criteria for the identification of biosphere reserves, special attention was paid to the embodiment of ecological and genetic principles of nature conservation, and thus the shape and size of reserves were considered important. In addition, criteria were determined for establishing a network of base-

line monitoring stations in representative undisturbed biome areas throughout the world to serve as benchmarks or standards for assessing change. Unlike many other forms of conservation reserve, biosphere reserves are intended to not only include natural ecosystems within national parks and wilderness areas but also seminatural systems, including, for instance, those maintained by long-established land-use practice. Each biosphere reserve should include one or more of the following categories: representative examples of natural biomes; unique communities or areas with unusual natural features of exceptional interest; examples of harmonious landscapes resulting from traditional patterns of land use; and examples of modified or degraded ecosystems capable of being restored to more natural conditions. Each biosphere reserve should be large enough to be an effective conservation unit with long-term legal protection and to accommodate different uses without conflict. In some cases biosphere reserves coincide with or incorporate existing or proposed protected areas, such as national parks, sanctuaries, or nature reserves.

Biosphere reserves are divided in up to four management zones:

A natural or core zone managed for minimum human interference, to serve as a baseline for the biological region and in which research, educational and training activities are carefully controlled and must be nonmanipulative.

A manipulative or buffer zone managed for research, education, and training activities, where manipulative methods and techniques are permitted. Traditional activities including timber production, hunting, fishing, and grazing, are permitted in a controlled manner.

A reclamation or restoration zone managed to study and reclaim lands and natural resources where heavy natural or human-caused alteration have passed ecological thresholds, where biological processes have been interrupted, or where species have become locally extinct.

A stable cultural zone managed to protect and study ongoing cultures and land use practices that are in harmony with the environment, including traditional land-use practices of indigenous peoples. In this zone local residents and their activities continue, but new technologies may be strictly controlled in order to minimize unwanted impacts.

Where it is not possible to have all the elements of the biosphere reserve in close contact with one another, a cluster arrangement of the components is permissi-

ble. However, it is still vital that other essential criteria are met, including adequate legal control, manageability and buffering of the core area. The concept of a core area is adapted to protect marine elements within a coastal biosphere reserve. A marine buffer zone can be established to help preserve marine core areas, as in the case of the zoning plan for the GREAT BARRIER REEF biosphere reserve in AUSTRALIA. Many biosphere reserves have been declared; nominations are approved by the International Coordinating Council of MAB.

## biosphere

THE ENVIRONMENT of the Earth can be broadly divided into four major systems: the atmosphere, hydrosphere, lithosphere, and biosphere. Russian scientist Vladimir Vernadsky coined the term *biosphere* in 1929. The term refers to the life zone of Earth that includes the air, land, and water occupied by all organisms including humans. This life zone distinguishes our planet from all others in the solar system.

The biosphere fulfills several important functions and processes to sustain life. These processes include the ways that solar energy and PRECIPITATION control biotic productivity, the interactions among various life forms, and how life forms have spread over the Earth's surface and adapted to various habitats. These processes are not limited to only the biosphere, but are the result of complex interactions between all the major systems (the atmosphere, hydrosphere, and lithosphere).

For example, the biosphere is both a source and sink for several important atmospheric trace gases and environmental pollutants (methane and nitrous oxide, for example). It is an essential factor in determining the budget, abundance, and distribution of trace gases in

the atmosphere. Different types of forests create different atmospheric conditions that influence climate and ecosystem functioning. Chemical reactions critical to both life and atmospheric processes include photosynthesis and respiration.

Water is essential for all living organisms, and the biosphere plays a crucial role in the transportation, transformation, and redistribution of water on local and regional scales. In terrestrial ecosystems, vegetation plays the primary role in transferring water from the soil to the atmosphere. The biota exerts measurable effects on water quality through recycling of nutrients and absorption of air and water pollutants. Biospheric processes are also evident in the lithosphere. Root growth and the generation of organic acids aid in chemical and mechanical weathering of soils and geologic materials. Decomposition of organic material add nutrients to the soil.

The biosphere is based on the hierarchical concept of a food chain. Primary producers (plants), herbivores, carnivores, and decomposers all interact to create food chains. Organisms are linked to their environment and their relationships with other organisms as energy and mass are transferred from one level of the food chain to another. All life is dependent upon the first tier of the food chain, the primary producers or plants. The amount of new energy acquired by plant life in a given time is the primary productivity of that unit.

The biosphere can be divided into distinct ECOSYSTEMS based on the interactions between organisms, the local food chain and their habitat and measured in primary productivity. This creates geographically diverse areas in the form of different physical environments (ecoregions), physiognomic types (BIOMES) and floristic and faunistic (biogeographic) zones. Primary productivity influences the number and type of animals that can live in a particular area. The quantity and variety are greatest where conditions are best for plant growth but decline under harsher conditions. The variety of these natural areas are represented by mountains, plains, coastal regions, islands, inland forests, deserts, tropics, tundra, polar areas, and oceanic realms.

Humans are also part of the biosphere. Human activity and impacts have led to changes in habitat and a reduction in biodiversity. Biosphere reserves have been created to demonstrate integrated management of land, water, and biodiversity in a coordinated network of protected areas. These reserves are characterized by a diversity of plants, animals and microorganisms and healthy natural ecosystems integrated with human sys-

tems and activities. Addressing the relationship between natural processes and human activities has been a critical aspect of understanding sustainable use by humans of the biosphere.

## Black Sea

THE BLACK SEA IS a body of salt water that stretches 630 mi (1,014 km) from east to west. TURKEY faces its southern shore, BULGARIA and ROMANIA lie west of the Black Sea, and UKRAINE, RUSSIA, and GEORGIA border it to the north, northeast, and east, respectively. The Black Sea stretches 330 mi (530 km) from north to south, except between the Crimean Peninsula and Turkey, where it cinches to 144 mi (232 km).

From the southwest, the Bosphorus connects the Black Sea to the Sea of Marmara, and to the north, just east of the Crimean Peninsula, the Kerch Strait leads to the Sea of Azov. The CAUCASUS MOUNTAINS line the northeastern edge of the Black Sea; the Pontic Mountains are to the south. The Black Sea is usually considered the boundary between Europe and Asia. At its deepest point, the Black Sea reaches a depth of 7,218 ft (2,200 m). It has an area of 262,840 square mi (683,000 square km). Below 660 ft (200 m), the water holds no oxygen, and the Black Sea is therefore the largest anoxic basin in world, with about 90 percent of its water permanently anaerobic. The Black Sea figures in myth and history, dating back thousands of years. In the *Voyage of the Argonauts*, Jason sails through the narrow Bosphorus, with shifting walls that threaten to crush his ship, into the Black Sea.

The sea, named "black" by the Turks for its storms, was the trade passage to Asia for the Egyptians and Greeks. It was important to the growth of Byzantium (now Istanbul) from 600 B.C.E. through the time of the Crusades, when the Byzantine Empire was finally destroyed. The Ottoman Turks controlled the Black Sea from 1453 to 1774.

Some evidence exists that the modern Black Sea was formed during a massive flood, perhaps Noah's flood.

Over 160 million people live in the area of the Black Sea, and it serves as a thoroughfare for oil tankers and other vessels. The sea's anoxic nature aggravates problems of pollution. The countries bordering the Black Sea, as well as the NORTH ATLANTIC TREATY ORGANIZATION (NATO) and other groups, are identifying the problems and proposing improvements in the ecosystems of the region.

In the 1990s, two geologists at Columbia University in New York City, William Ryan and Walter Pitman, proposed a new theory: that the Black Sea had been a freshwater lake until 5000 B.C.E. The MEDITERRANEAN SEA swelled, flooded northward over Turkey, and funneled through the Bosphorus Strait with an impact greater than 200 times the force of Niagara Falls. During this flood, which is recalled in the Bible, the Gilgamesh Epic of Sumer, and other ancient stories, the Black Sea rose at a rate of 6 in (15 cm) a day. Dr. Robert Ballard, discoverer of the *Titanic* remains in 1986, headed an exploratory team in 1999 and 2000 that found evidence of an ancient shoreline 550 ft (168 m) below the current level of the Black Sea. Preliminary dating of sediment supports the flood theory of Williams and Pitman, and Ballard has also found ancient river channels and the remains of a wooden structure 311 ft (95 m) below the current surface.

INDEPENDENT SCHOLAR

## Bokkara

**BOKKARA (ALSO BUKHARA)** is a city that lies on the SILK ROAD of Central Asia in the Asian republic of UZBEKISTAN. Its name, bestowed by its Sogdian occupiers in the 3rd century B.C.E., derives from the Sanskrit word *vikhara*, meaning "monastery." Bokkara lies in the ARAL SEA basin and was founded some 3,000 years ago by the Persian Prince Siyavush of the Syavushid dynasty on a hill in the Kyzyl Kum, a desert region in the northern foothills of the Pamir/TIAN SHAN MOUNTAINS. It enjoys a continental climate of cold winters and hot summers. The annual temperature regime varies from 5 degrees F (-15 degrees C) in January to 126 degrees F (52 degrees C) in July and receives less than 8 in (20 cm) of precipitation per year.

Culturally, Bokkara has experienced many influences because of its location at the crossroads of Asia. The Achaemenids of Persia captured Bokkara 2,600 years ago, it was taken by Alexander the Great in 329 B.C.E., and then by the Sogdians from the Fergana and Zerafshan valleys to the east. At this time, Zoroastrianism, a belief system involving fire worship, was practiced. However, with the arrival of the Arabs, the city changed and ISLAM was introduced.

### ISLAMIC LEGACY

This Islamic legacy is apparent today in the form of mosques, *madrassas* (Islamic schools), and the minarets, palaces, and mausolea of the ruling elite and their successors, the Samanid dynasty. In the early 13th century, the Mongols, led by Genghis Khan, invaded and destroyed much of Bokkara. In 1500, the Uzbek people claimed Bokkara, routing the descendants of the great Tamar (also Amir Timur and Tambulaine) who had established his capital at SAMARQAND in the early 1400s.

The decorative arts were encouraged, especially miniatures, and the restoration of Bokkara's ruined buildings commenced. The city benefited from overland intercontinental trade as commerce was established between eastern Asia and western Europe. Various wars and rivalries then led to a decline in the city's fortunes until the 1800s when British and Russian interests were revived as they vied for influence and attempted to reestablish trade.

### SOVIET ERA

Tzarist interests caused another twist in Bokkara's history, and that of the region in general. Russian interest intensified, though Bokkara never formally became part of the empire until the advent of the Soviet era in 1924, when Uzbekistan, as a political unit of the Soviet union, was created. Cultural change was generated through education, but the underlying traditions of Bokkara were never extinguished. Commerce and trade remained important and Islam remained the chief religious influence. Even though many of the ancient mosques were closed by the Soviets, they were not destroyed. Today, in the independent, post-Soviet era, the monuments associated with Bokkara's rich history provide the attraction for a growing tourist industry, and many are working mosques once again.

## Bolivia

**Map Page** 1139 **Area** 424,164 square mi (1,098,580 square km) **Population** 8,586,443 **Capital** La Paz **Highest Point** 21,463 ft (6,542 m) **Lowest Point** 295 ft (90 m) **GDP per capita** \$2,500 (2002) **Primary Natural Resources** tin, natural gas, petroleum, zinc.

BOLIVIA IS A COMPLEX and fascinating country. Located in the center of South America, it shares bor-

ders with five countries: ARGENTINA, BRAZIL, CHILE, PARAGUAY, and PERU. After the War of the Pacific (1879–84) against Chile, Bolivia lost access to the PACIFIC OCEAN and became, along with Paraguay, one of the two LANDLOCKED states in the Americas. Since then, the question of Bolivia's access to the sea has remained a central diplomatic and economic issue in the region. In addition, in 1935, during the Chaco War against Paraguay, Bolivia lost substantial claims to the Chaco territory.

Bolivia is a contradictory country. While it is extremely rich in natural resources, including some of the largest reserves of natural gas and tin, it has acute social and economic tensions. The country's economic vulnerability, its cycles of boom-and-bust, and its traditional dependence on the external market have intensified social inequality. At the beginning of the 21st century, with two-thirds of the country's population living in poverty, a third of which falls below the poverty level, Bolivia is one of the poorest nations on the continent. After a short period of economic growth in the 1990s, the economy slowed down as result of the Asian economic crisis, and social and political tensions have consistently increased.

Geography and the environment have shaped the history of Bolivia. Bolivia has three distinctive geographical regions: the highlands or ALTIPLANO (high plateau), the transitional sub-Andean, and the tropical lowlands. The majority of the Bolivian population has historically lived in the Altiplano, between 12,000 ft (3,657 m) and 13,000 ft (3,962 m) above sea level. The altitude has posed enormous challenges.

In pre-Columbian times, the Andean poor soils, high altitude, and harsh climate forced the population to develop new agricultural techniques and domesticate the American cameloids (llama and alpaca). On the eve of the Spanish conquest, the Bolivian Andes produced about 200 kinds of potatoes. The highlands have provided essential mineral resources including one of the richest silver mines in the world, Potosí. The Altiplano also has the world's highest navigable lake, Lake TITICACA (12,483 ft or 3,805 m), which Bolivia shares with Peru. The valleys of the transitional sub-Andean region have been a significant source of agricultural products and the basis of a peasant tradition.

Despite the image of Bolivia as an Andean country, about two-thirds of its territory is tropical or semi-tropical. Access to the tropical lowlands, however, has been traditionally difficult, limiting the demographic growth and the exploitation of economic resources. In the late 19th century, the exploitation of rubber created

*La Paz is the de facto capital of Bolivia and where the seat of government is located.*

an economic boom in the area, and since the last decades of the 20th century, the development of commercial agriculture, including products such as sugar, cotton, and cattle, have promoted enormous growth. Today, the tropical regions and its major city, Santa Cruz de la Sierra, are among the fastest-growing areas in the country.

Since the mid-1950s, Bolivia has become an increasingly urban country, and today about 62 percent of the population lives in cities. While Sucre is the official capital, La Paz is the de facto capital and the seat of the government. La Paz has an estimated population of 793,293 people, and El Alto, a former suburb of La Paz, has about 649,958 residents and an annual growth of 5.1 percent. Santa Cruz de La Sierra, located in the tropical eastern lowlands, has become in the last decades an important urban and economic center, and today it has an estimated population of 1,135,526 and an annual urban growth of 5.08 percent.

Bolivia is a multiethnic society. About 55 percent of the population is considered of native origin, 30 percent of which is Quechua and 25 percent Aymara. The native heritage has shaped popular culture, traditions, folklore, festivals, language, and religious practices. Another 30 percent identified themselves as mestizo or *cholos*, an ambiguous category that refers both to people of mixed race as well as acculturated natives who live in urban environments, speak Spanish, and have abandoned native customs and dress. Only approxi-

mately 15 percent of the Bolivian population is classified as white.

## Bordeaux

BORDEAUX IS THE eighth-largest city in FRANCE, and the capital of the historic southwestern province of Aquitaine. Bordeaux is also considered the wine capital of the world, and has been famous for its viticulture since the days of the Roman Empire. Unlike other major French cities, Bordeaux is not known for its energetic lifestyle or major industrial output; instead, the Bordelais take pride in their region's more relaxed pace of life and the spirit of elegance and refinement that characterizes much of the city and the region.

The city of Bordeaux arose as a Gallo-Roman port (Burdigala) on the river Garonne at the head of the large estuary the Gironde, which flows into the ATLANTIC OCEAN about 56 mi (90 km) to the northwest. It became the chief city of Aquitaine from the early Middle Ages, before this region became part of the kingdom of France. In fact, from 1152 to 1453, Bordeaux was an English city, the jewel in a string of French possessions held by the English kings until they were finally chased out at the end of the Hundred Years' War. Even after this date, Bordeaux remained the chief supplier of wine to England and other northern European states.

The city's wealth continued to grow with the development of Atlantic sea trade in the 17th century, primarily through the growth of refineries for sugar, which arrived in Bordeaux's ports directly from France's colonies in the West Indies. Revenues from the sugar and wine industries reshaped the city, which underwent a massive urban renewal in the 18th century, resulting in much of the city's present appearance, notably the Place Royale (today's Place de la Bourse) and the Grand Théâtre.

Today's Bordeaux is a varied mixture of medieval churches, 18th-century squares, and more modern de-

velopments such as the massive suspension bridge across the Garonne, the Pont d'Aquitaine, opened in 1967. Several Gothic churches dominate Bordeaux's skyline owing to a general lack of skyscrapers. Notable among these is the Cathedral of Saint-André and the basilicas of Saint Seurin and Saint-Michel, all three of which were declared United Nations World Heritage sites in 1998 as important stops on the pilgrimage routes to Santiago de Compostela. Renaissance and neoclassical buildings include the Grosse Cloche, a tall clock tower that is one of the symbols of the city, and the Palais Rohan, the former archiepiscopal palace and now the city hall. Louis XV residences in Bordeaux are among the finest of French architecture.

In 2000, a plan was introduced to renovate the Garonne quaysides, which stretch for miles in a graceful unified arc along the curve of the river. City improvements such as this continue to be funded by wine revenues. Bordeaux's 57 different appellations (varieties) of wine are produced on roughly 20,000 acres (8,000 hectares) of surrounding countryside by 3,000 independent chateaus, 60 wine cooperatives, and the city's 400 wine merchants. The city's population is nearly 219,000 (1999). Many residents are occupied in some form with the wine industry but increasingly are also employed in aeronautics and aerospace technologies and the manufacture of chemical and pharmaceutical products.

## Borneo

THE ISLAND OF BORNEO is the largest island of the Malay archipelago and the third-largest island in the world (after GREENLAND and PAPUA-NEW GUINEA), covering 287,420 square mi (736,974 square km). It is also one of the least explored places on Earth and retains much of the mystery for today's tourists that it did for anthropologists and adventurers of the 19th century. Borneo is not a single political unit; rather, it is

divided among three countries: 72 percent of the island, known as Kalimantan, is a province of INDONESIA. The rest forms the two eastern provinces of MALAYSIA, Sabah and Sarawak, plus the small independent sultanate of BRUNEI.

Unlike most of its island neighbors, Borneo is not entirely volcanic in origin, but formed of ancient igneous rock. It is seen more as an extension of the continental landmass of Southeast Asia, separated only by the Sunda Sea, which is very shallow (656 ft or 200 m) and was probably dry land in the geologically recent past. This is in contrast to the deep plunges of the waters to the east and south of the island, the Sulu and Celebes seas, and the Selat Makasar.

Borneo is crossed by two main mountain chains, which roughly divide the island into four watersheds. Three of these cover Kalimantan, while the fourth, that of the northwest, waters Sabah, Sarawak, and Brunei. The main range, like a backbone, crosses the island diagonally from southwest to northeast and consists of the Kapuas and Iran ranges—which form the boundary between the Indonesian and Malaysian parts of the island—continue in the south as the Schwaner range. These ranges have several peaks over 6,600 ft (2,000 m), but the highest mountain on the island (and in Southeast Asia), Kinabalu (13,533 ft or 4,101 m), stands on its own at the far northern point of the island. The volcanic Kinabalu is one of the leading spots in the region for tourists, drawn to its hot mineral springs and exotic wildlife, including the Rafflesia, the largest flower in the world (up to 66 in or 170 cm in diameter).

The coasts are almost entirely alluvial and swampy, especially in the south and southeast. This area is one of the best watered in the world, with frequent rains and numerous rivers and streams. But most are obstructed by mud and vegetation, and navigation for larger vessels is hindered by swamps at most river mouths, spreading across vast DELTAS, some reaching up to 70 mi (113 km) across. During the rainy season, for example, the Barito River in the southeast covers a delta of roughly 11,000 square mi (28,000 square km).

The equator cuts directly across the island, and its vegetation reflects this geographic position. Most of the area is covered with thick forests and dense vegetation. The forests contain valuable tropical hardwoods like teak, ebony, and sandalwood, the best camphor in Asia (a tree resin used to make medicines), and spices such as nutmeg, ginger, cinnamon, clove, and pepper. The forests also contain many large wild animals, such as the Asian elephant, gibbon, tapir, the giant python

(which grow up to 20 ft), and the so-called man of the forest, the orangutan. Deforestation is a serious problem, however, causing both erosion and loss of habitat for these increasingly rare animals. Especially bad in Kalimantan, out-of-control forest fires have burned continuously since 1983, destroying millions of acres. These fires are sometimes set deliberately by farmers or loggers clearing small plots, but they are fueled by underground coal deposits, creating searing temperatures that roast the subsoil.

Borneo is also incredibly rich in minerals, including gold, coal, copper, platinum, and diamonds. There is a significant amount of petroleum on the east coast near Tarakan and Balikpapan and on the west coast near Miri (Sarawak) and Seria (Brunei). This wealth of natural resources is a source of economic strength for Brunei and eastern Malaysia, and a source of potential disintegration for Indonesia, as the outer islands seek greater autonomy from overcrowded and proportionately resource-poor JAVA.

Most of the population clusters along Borneo's rivers, as the coasts are too swampy and the interior too rugged. The indigenous people, known collectively as Dayaks, are divided into numerous tribes and live in various degrees of contact with other, nonindigenous peoples. Some were known as recently as the 1970s to practice ritual headhunting, but the practice has officially ceased.

Malayan people have had settlements and kingdoms on Borneo from about the 13th century, roughly the same time as the arrival of the third main group who populate Borneo, the Chinese, who dominated trade in the region for centuries. Dutch and British trading companies vied for dominance in the 18th and 19th centuries, with the Dutch ultimately controlling the southern three-fourths of the island, and the British controlling the north, including the sultanate of Brunei (a protectorate from 1888), the territory of the "White Rajah," James Brooke (Sarawak), and the world's last sovereign corporate-run state, British North Borneo (Sabah, governed until 1946 by the British North Borneo Provisional Association, Ltd.).

Rubber plantations were established by the British and the Dutch, but it was palm oil that became the backbone of colonial export, used to produce things like margarine and soap. Dutch Borneo became part of the independent Republic of Indonesia in 1949, while Sabah and Sarawak joined with Malaya to form Malaysia in 1957. Brunei remained a protected British state until 1984. Malays now form a larger percentage of the population on account of the exodus of large

numbers of Chinese from both Malaysia and Indonesia in the face of growing xenophobia and Islamicism.

## Bosnia and Herzegovina

**Map Page** 1133 **Area** 19,940 square mi (51,129 square km) **Population** 3,989,018 **Capital** Sarajevo **Highest Point** Maglic 7,826 ft (2,386 m) **Lowest Point** 0 m **GDP per capita** \$1,900 **Primary Natural Resources** coal, iron, bauxite, zinc, hydropower.

**BOSNIA AND HERZEGOVINA** was one of the component states of the former federation of Yugoslavia until it declared its independence in March 1992. Its ethnic and religious makeup had become so intertwined under the forced egalitarianism of Josip Tito that divisions and tensions between the country's three major groups—Bosnians, Serbs, and Croats—immediately turned to violence, as each nationality sought to carve out a portion of the country's territory for themselves.

The ensuing conflict caused the deaths of somewhere between 60,000 and 200,000 people and displaced about half the population. Since the peace agreements made in Dayton, Ohio, in December 1995, the country has been partitioned into two federated units, the Federation of Bosnia and Herzegovina and the Republika Srpska (Bosnian Serb Republic). Foreign troops sent in by the NORTH ATLANTIC TREATY ORGANIZATION (NATO) and by RUSSIA keep an uneasy balance, while the country's overall administrative affairs are overseen by a EUROPEAN UNION high commissioner.

Bosnia and Herzegovina occupies a mountainous central zone of the Balkan Peninsula, surrounded on all sides by other former members of Yugoslavia: CROATIA

to the north and west, and SERBIA AND MONTENEGRO to the west and south. The country has a tiny outlet to the ADRIATIC SEA, 18 mi or 29 km, wedged between portions of the long Croatian (Dalmatian) coast.

Although some of its rivers flow westward into the Adriatic, notably the Neretva, most Bosnian rivers flow east and north from the watershed of the Dinaric Alps into the Danube basin. These include the Sava, which forms the northern border with Croatia, its tributary the Drina, which forms part of the eastern border with Serbia, and other tributaries of the Sava, the Vrbas, and the Bosna, which gives the country its name. The other half of the country's name, Herzegovina, comes from an ancient feudal division of the region, this part being held by a duke (*herzeg* is a Slavic corruption of the German word for "duke," *herzog*).

Bosnia is much larger than Herzegovina, and although the population is mostly the same, the landscape is different. Herzegovina tends to be drier, rockier, with a Mediterranean climate, versus the more continental climate of the Bosnian interior. Sarajevo, the capital, is roughly in the center of the country, on the Bosna River. Other cities include Banja Luka, Tuzla, Bihac, and Mostar, the capital of Herzegovina. The only area of relative flatness are the plains along the Sava river valley in the far north.

## OTTOMAN EMPIRE

Ever since it was settled by Slavic tribes in the 7th century, the region has been dominated and contested by its more powerful neighbors, the Hungarians, the Croats, and the Serbs, with the exception of an independent Bosnian kingdom in the 14th and 15th centuries. The entire Balkan peninsula was incorporated into the empire of the Ottoman Turks dating from the 15th century, but unlike many of its neighbors, a large number of the Bosnian Slavs converted to ISLAM, for reasons ranging from genuine religious conviction to tax breaks and political advancement.

Today's Bosnians are descendants of these people, and differ from their Croat and Serb conationalists mostly in terms of religious affiliation, despite the fact that most Bosnians consider themselves only minimally religious. The Serb and Croat languages are nearly the same, but Serbians use the alphabet of their Orthodox faith, while Croat Catholics use the Latin alphabet. Even after the Dayton Agreement of 1995, the populations have continued to separate along ethnic lines, whereas twenty years ago, ethnic intermarriages were more common than not, almost one in three. The Federation of Bosnia and Herzegovina, primarily popu-

lated by Croats and Bosnians, and the Republika Srpska, populated by ethnic Serbs, are both oddly shaped—the latter (with roughly 50 percent of the land) wraps around the former—and include several ENCLAVES within each other, such as the internationally supervised district Brcko.

The wars of the 1990s and subsequent mass emigration has destroyed most of Bosnia's economy and left nearly 45 percent of the population unemployed. Even before the breakup of Yugoslavia and ethnic strife, Bosnia and Herzegovina was (along with Macedonia) the poorest region of the federation. Its economy had been focused not on food production, but chiefly on machinery and military supplies for the rest of Yugoslavia. Bosnia has a good supply of natural resources, including coal, iron, copper, and timber, which could form the core of a revived national economy.

## Botswana

**Map Page** 1116 **Area** 231,803 square mi (600,370 square km) **Population** 1,573,267 **Capital** Gaborone **Highest Point** 4,890 ft (1,491 m) **Lowest Point** 1,682 ft (513 m) **GDP per capita** \$8,800 **Primary Natural Resources** diamonds, copper, silver.

BOTSWANA IS a LANDLOCKED country in southern Africa, approximately 310 mi (500 km) from the nearest coastline to the southwest. Although two-thirds of Botswana is within the tropics, the landscape is dominated by the KALAHARI DESERT (after the Setswana name *Kgalagadi*), a sand-filled BASIN averaging 3,607 ft (1,100 m) above sea level.

Botswana is bordered by ZAMBIA and ZIMBABWE to the northeast, NAMIBIA to the north and west, and

SOUTH AFRICA to the south and southeast. At Kazungula, four countries—Botswana, Zimbabwe, Zambia and Namibia—meet at a single point midstream in the Zambezi River in the extreme northeast. If it were not for an interesting strip of land in the north, the Caprivi Strip, Botswana might also have a border with ANGOLA. The Caprivi is a narrow strip of land in the far northeast of Namibia that is about 250 mi (400 km) long and forms the Namibian part of the border with Botswana. Germany exchanged the area (together with Helgoland) with the UNITED KINGDOM for Zanzibar in 1890. It was named after the German chancellor of the time, Graf von Caprivi, who signed the contract with the British.

### BOTSWANA RIVERS

The Chobe River runs along part of Botswana's northern boundary; the Nossob River at the southwestern boundary; the Molopo River along the southern boundary; and the Marico, Limpopo and Shashe rivers at its eastern boundaries. Like the Okavango and Zambezi rivers, the Chobe's course is affected by fault lines, which are extensions of East Africa's Great Rift Valley. Taken together, these three rivers carry more water than all other rivers in southern Africa combined. Except for the Okavango and Chobe areas in the north, the country has little permanent surface water.

The eastern hardveld (hard-surfaced grazing area), where 80 percent of the country's population lives and where its three largest urban centers are situated, is a wide strip of land running from the north at Ramokgwebane to the south at Ramatlabama. It has a more varied relief and geology with inselbergs (outcrops of resistant rock) and koppies (rocks that have been weathered into blocks) dotting the landscape. The southeastern hardveld has a slightly higher and more reliable rainfall than the rest of the country, and the natural fertility and agricultural potential of the soils, while still low, are greater than in the Kalahari sandveld (sand-surfaced grazing area).

### THE KALAHARI

The Kalahari Desert stretches west of the eastern hardveld, covering 84 percent of the country. The word *desert*, however, is a misnomer. Most of the Kalahari is covered with vegetation, including stunted thorn and scrub bush, trees and grasslands. The largely unchanging flat terrain is occasionally interrupted by gently descending valleys, sand dunes, isolated hills in the extreme northwest, and large numbers of pans that fill with water during the rainy season. These pans are of

great importance to wildlife, which obtain valuable nutrients from the salts and the grasses of the pans.

In the northwest, the Okavango River flows in from the highlands of Angola and soaks into the sands, forming a 5,791 square mi (15,000 square km) network of water channels, lagoons, swamps and islands. The Okavango is the largest inland DELTA system in the world, just slightly smaller than ISRAEL in size.

Although Botswana has no mountain ranges to speak of, the landscape is occasionally punctuated by low hills, especially along the southeastern boundary and in the far northwest.

### HISTORY

Formerly the British protectorate of Bechuanaland, Botswana adopted its new name upon independence in 1966. San (Bushmen) were the aboriginal inhabitants of what is now Botswana. Beginning in the 1820s, the region was part of the expansion of the Zulu and their offshoot, the Ndebele.

In the late 19th century, Boers (Afrikaners) from neighboring Transvaal spread into the region as gold was discovered. With the Boers continuing to encroach on native lands during the 1870s and 1880s and German colonial expansion pressing into South-West Africa (Namibia), the British were forced to reexamine their policies and established Bechuanaland as a protectorate in 1885. The southern part of the area was incorporated into Cape Colony in 1895, where a resident commissioner administered it until 1961. Although Bechuanaland had no nationalist movement, Britain granted it internal self-government in 1965 and full independence as Botswana on September 30, 1966.

Agriculture still provides a livelihood for more than 80 percent of the population but supplies only about 50 percent of food needs and accounts for only 3 percent of the country's gross domestic product (GDP). The country's water shortage and lack of sufficient irrigation facilities has severely hampered agriculture development, and only a small percentage of the land is under cultivation. Where there is sufficient water, corn, sorghum, millet, and beans are the principal subsistence crops, and cotton, peanuts, and sunflowers are the main cash crops. Cattle raising and mining dominate the economy.

At the time of independence, the only known minerals were manganese and some gold and asbestos. Since that time, large deposits of nickel and copper have been found, as well as salt and soda ash. Vast coal deposits are also being worked, and antimony and sulfur are known to exist. Botswana's three diamond

mines collectively make up one of the largest diamond reserves in the world. The stones are mined by the government and a South African mining concern, providing a strong link between Botswana's well-being and South Africa. Deposits of plutonium and platinum are also known to exist, but are as yet undeveloped.

Although Botswana's mineral wealth has made it one of the wealthiest nations of southern Africa, high unemployment remains a problem. Development of the tourist industry has been growing, based partly on the country's game reserves. Because of its landlocked position, Botswana remains heavily dependent on South Africa for the provision of port facilities.

## boundaries, natural

GOVERNMENTS USE physical features as boundaries of political units: boundaries of countries, states, counties, cities, and so forth. (Not all political boundaries follow natural features. A boundary can be geometric, meaning it is composed of straight-line segments and arcs. There is a cultural type of boundary, as well. This boundary usually separates different ethnic groupings. There are also historical boundaries, which are natural, geometric, and cultural relicts of former political entities.) A natural feature, such as a river or mountain range, is a logical choice, as it is visible and tends to interfere with human movement and interaction. Natural features as political boundaries have advantages and disadvantages for various reasons that we will examine in the next section.

A second type of natural boundary—the boundary of a natural region—separates areas with certain dis-

tinctive types of landforms, climates, ecosystems, and so on. Geographers and other scholars often study landscapes within the confines of natural regions, so their boundaries are important. In the early 20th century, geographers and political ideologists merged the boundary of the natural region with the political theory of the organic state. The idea of an organic state with “natural” boundaries influenced Adolf Hitler's dictatorship of GERMANY.

### BOUNDARY OF A POLITICAL UNIT

When a political boundary conforms to some feature of the physical landscape—a stream, sea, mountain, desert, watershed, lake, marsh, and so forth—it is a natural boundary. Natural features have dimensions of length and breadth, whereas political boundaries are lines of separation. Consequently, two countries that share a natural boundary must agree on a method of marking a boundary line.

Across open land, such as along the crest of a mountain range, a mere line of poles, stones, or cement markers usually suffices. Buoys mark the boundary line if it passes along or across a large lake. Small lakes and narrow rivers may not have any clear demarcation, unless the boundary follows the water's edge. Boundary lines that use physical features are often difficult to survey. Several boundary commissions may be required to work at the setting up boundaries, employing detailed surveying and mapping information, before the involved states are satisfied.

### FRONTIER BOUNDARIES

Frontiers often function as natural boundaries. Frontiers are vast unsettled or underpopulated areas that separate and protect countries from each other. The inhospitable nature of frontiers impedes governmental control. Examples of frontiers are expansive deserts, marshes, oceans, frigid lands, dense forests, and rugged mountains. The spread of control from a country's political core area into a frontier gradually eliminates its boundary function.

CHILE is an example of a country that developed while surrounded by frontiers. Chile's political core was in Santiago Valley; the Atacama Desert lay to the north, mountainous ANDES to the east, frigid land to the south, and the PACIFIC OCEAN to the west. From Santiago Valley, the government extended its hegemony into the northern and southern frontiers. The Andes Mountains are a remaining frontier, as they still function as a natural boundary between Chile and ARGENTINA due to their awesome physical presence.

Historically, countries chose natural boundaries for their defensibility against attack from their neighbors. Modern military technology has reduced the defensive function of mountains today. The only exceptions tend to be the more rugged mountainous areas, where military advantage shifts toward controlling summits and key passes that are more defensible. The HIMALAYAS between INDIA and CHINA and the aforementioned Andes between Chile and Argentina are outstanding examples of defensible mountain boundaries.

Regardless of the decline in defensibility of natural boundaries, they remain part of the international political map. In many instances, historical and legal precedence preserve their usage. In other cases, such boundaries are still valuable for their barrier effect: They reduce the potential amount of friction brought on by past hostilities, as well as smuggling or illegal immigration.

### RIVERS AND LAKES AS BOUNDARIES

Rivers play a dual and contradictory role in the political state. Since the earliest civilizations, some rivers have united people more than they separated them. In early Mesopotamia, the Tigris and Euphrates rivers were highways of internal trade, commerce, and communication. Ease of transportation was crucial when riverine states in this region were in the process of formation, for this, in no small degree influences the extent of the political domain. The same was also true of the NILE in early EGYPT. The RHINE (in Europe), and the MISSISSIPPI (in the UNITED STATES), IRRAWADDY (in MYANMAR), Menam Chao Phraya (in THAILAND), Mekong (in VIETNAM and CAMBODIA), and Hwang Ho (in CHINA) play key roles as national unifiers today.

About one-fifth of the world's political boundaries are rivers. The actual boundary lines of rivers follow along either a bank or the mid-channel of a stream. Most river boundaries are of the mid-channel type in order to assure shared usage by adjoining political units. Lakes, for the same reason, tend to have divisional boundaries. The Canada-U.S. boundary divides the Great Lakes and the CALIFORNIA-NEVADA boundary does the same for Lake Tahoe. The CASPIAN SEA (actually a lake) in Central Asia, Lake VICTORIA in Africa, and the Bodensee (Lake Constance) in the ALPS are prominent international lakes.

Rivers in particular do not make perfect boundaries. They give the illusion of permanence on a map—a trait valued by boundary makers—but stream courses do change. For instance, the Mississippi, which for most of its length is a U.S. interstate boundary line,

has varied its course frequently, leaving parts of the left bank on the right side of the line and vice versa.

The international wanderings of the RIO GRANDE have made the problem of unstable river courses famous. An 1853 survey drew the boundary between the U.S. state of TEXAS and MEXICO down the middle of the Rio Grande. The first of a series of disputes came in the wake of floods in 1864, which caused a change in the river's course that left a chunk of 630 acres (about 1 square mi or 2.6 square km) of land north of the river. Several other wanderings resulted in losses or gains of land for both countries in the ensuing years. As the region became more populated, control of the boundary was more difficult.

In 1884, the two countries agreed that the boundary should follow the abandoned river channel whenever the river changed course. This meant that the area transferred from one bank to the other would remain under the sovereignty of the original state. However, this policy diminished the function of the river as a boundary. In 1905, in order to protect the integrity of the river as the boundary, the governments agreed to exchange land cutoff by the river, but only if the land area or the number of people living there was sufficiently large. Otherwise, the river channel would remain the boundary. A permanent commission was also set up to determine exchanges.

In the 1960s, the two governments finally stabilized the channel with concrete. Land claim problems along the border are rare today. The stabilization of the rivers like the Rio Grande is exceptional. Around the world, meandering rivers create potential boundary problems such as the Rio Grande did. Other disputes evolve around repositioning boundaries so that rivers become boundaries. The list below contains examples of rivers and lakes that are the bases of recent boundary disputes.

Amazon and Marañon rivers (ECUADOR and PERU)  
 Amur River (China and RUSSIA)  
 Atrak River (KYRGYZSTAN and TAJIKISTAN)  
 Belesa-Mareb-Setit Rivers (ERITREA and ETHIOPIA)  
 Caspian Sea (AZERBAIJAN, IRAN, KAZAKHSTAN, Russia, and TURKMENISTAN)  
 Congo/Zaire River (Democratic Republic of the CONGO and Republic of the Congo)  
 Essequibo River (GUYANA and VENEZUELA)  
 Ganges-Brahmaputra-Meghna rivers (India and China)  
 La Plata River (BRAZIL and URUGUAY, and Brazil and PARAGUAY)

Lake Chad (CAMEROON, CHAD, NIGER, and NIGERIA)  
 Lake Malawi (MALAWI and TANZANIA)  
 Lake Tanganyika (Democratic Republic of the  
 Congo, ZAMBIA, and Tanzania)  
 Linyanti River (BOTSWANA and NAMIBIA)  
 Maroni River (SURINAME and FRENCH GUIANA)  
 Mekong River (LAOS and Thailand)  
 New River (Guyana and Suriname)  
 Orange River (Namibia and SOUTH AFRICA)  
 Sara and Una rivers (BOSNIA-HERZEGOVINA and  
 SERBIA, and HUNGARY and SLOVAKIA)

### MOUNTAINS AS BOUNDARIES

Like rivers, mountainous areas may bring together a population, as in the northern Andes (COLOMBIA, Venezuela, Peru, and Ecuador), where heat and humidity drive people to the uplands. As mentioned earlier, historically, governments have held certain mountainous borders in high esteem, because as barriers, they defend a country by holding back or at least slowing down the enemy because of rugged terrain. Such borders are high, rugged, snow-covered, and glaciated and therefore, natural barriers to movement and communication.

Mountains are not ideal places to demarcate boundaries. Surveys may define the boundary along the highest crests (summits), the watershed (or divide), or points along the base of slopes. Additionally, boundary commissions have drawn many such lines after settlement of a mountainous region has already taken place, thereby separating people who share the same language or popular loyalties. A famous example of boundary superimposition happened after World War I. A postwar boundary commission had the task of carving out new countries from a defunct German-speaking Austro-Hungarian Empire. The commissioners drew the new southern border of AUSTRIA assiduously along the high mountain crest of the ALPS.

However, the line divided German speakers in the Alps's Tyrol region into two separate provinces. North Tyrol became part of Austria and South Tyrol part of ITALY. A similar problem of ethnic truncation arose in the Carpathian Mountains between POLAND and CZECHOSLOVAKIA. To the consternation of the people affected, the boundary commissioners did not rectify either problem; they claimed that the coincidence of high mountain crests with the parting of waters and the defensibility of the crests made perfect borders.

Disputes over mountain boundaries can lead countries to the brink of war. For instance, Argentina and Chile prepared for war in the late 19th century, as both

countries were dissatisfied with the Andean boundary they shared. At first glance, the Andes Mountains form what seems to be an ideal natural boundary separating the two countries. Unfortunately, a line joining the highest summits of the mountains does not always divide the watersheds. Particularly in the southern part of the boundary, where glaciers in Chile have eroded back the high ends of valleys to a point where they were well to the east of the line connecting the highest summits. Argentines argued that the highest summit line should cut across such valleys, meaning that eastern (high) ends of the valleys should belong to Argentina. Chileans saw it differently. They argued that the line should follow the drainage divide, meaning the boundary should loop around the high ends of the valleys, not pass from peak to peak straight across the valleys. Therefore, Chileans reasoned that the valleys should belong to Chile in their entirety. Ultimately the two countries agreed to ask the Queen of England to settle the dispute. The two countries agreed to a resolution in 1902. In gratitude for averting the war, the peoples of the two countries built a 26-foot-tall bronze Christ of the Andes statue in Uspallata Pass, the main route through the mountains between Buenos Aires and central Chile.

### OCEANS AS BOUNDARIES

Improved navigation of the seas brought about a concern for the legal status of the oceans and the ownership of marine resources in the 1600s. In 1672, the British claimed marginal waters as far as a cannon could hurl projectiles. Such a range was about 3 nautical mi (5.6 km). A judge of the Supreme Court of Holland added international credence to the distance in 1703, when he ruled that the same distance should be the legal limit of the territorial sea of all coastal countries.

The 3-mile limit remained the standard for most nations and the League of Nations formally accepted it in 1930. After World War II, as states turned increasingly to the seas for their resources as well as their transport and strategic value, international acceptance of the 3-mile limit began to unravel. A series of postwar treaties led to the 1982 United Nations Convention of the Law of the Sea (or Law of the Sea Treaty). Almost all the nations of the world have signed the 1982 convention. Nations view the Law of the Sea Treaty as generally reflecting customary international law, even by countries that have not signed it. The important points of the agreement can be summarized as follows:

*Territorial sea.* A coastal state's territorial sea can extend to 12 nautical mi (22 kilometers) from the shoreline. The state has full sovereignty rights to the air space above and to all resources in the sea, including those in the underlying seabed and subsoil. The coastal state controls access to the territorial sea by foreign nations. (Some nations, including Peru, Ecuador, SOMALIA, and the PHILIPPINES still claim territorial seas to 200 nautical mi despite the treaty.)

*Contiguous zone.* A coastal state may extend its legal right to control foreign vessels in a zone that is contiguous to its territorial sea. This zone can be up to 12 nautical mi (22 km) wide. As in the territorial sea, the country's customs and military agencies, as part of their regular duties, can authorize law enforcement personnel to board foreign vessels to search for and seize contraband (for example, illegal drugs or terrorists) or evidence of other alleged illegal activities.

*Exclusive economic zone (EEZ).* This zone normally extends out from the territorial sea to 200 nautical mi (370 km). However, the zone can extend as far as 350 nautical mi (649 km) to the edge of the continental shelf, if the shelf extends beyond 200 nautical mi. Within its EEZ, the coastal nation has sovereign rights over mineral resources, fishing, and environmental protection. The nation may exercise control over access to the zone for scientific research. It also has control over exploitation of resources, including the mining of minerals, drilling of oil, and the use of water, currents, and winds for the country's production of energy.

The United States has the world's largest EEZ, not because of its coastlines around the contiguous states, but because of the vast additional EEZ area contributed by ALASKA, HAWAII, PUERTO RICO, the U.S. Virgin Islands, and the various U.S. Pacific protectorates and islands, including American Samoa and Guam. As a result, the U.S. EEZ contains many of the world's most productive fisheries, and probably a large share of the mineral wealth of the oceans.

The cooperation of nations to define boundaries in oceans is a necessary and positive step toward avoiding conflicts involving offshore territory and marine resources. Nevertheless, sovereignty disputes over overlapping boundaries of territorial seas and EEZs are increasing political tensions in the world. Most disputes involve overlapping EEZs that surround tiny island nations located on a continental shelf, as such nations can control an EEZ greater than the size of Minnesota. The seas off the coasts of East and Southeast Asia provide many examples of EEZ disputes.

## BOUNDARY OF THE NATURAL REGION

R. Hartshorne (1939) describes how, during the late eighteenth and early nineteenth centuries, European geographers became interested in defining geography as a separate science and not a mere handmaiden of history and government. "In place of the definite areal units of states," Hartshorne writes, "sharply defined by political boundaries, the new geography required equally definite 'natural' units, somehow defined in nature."

Geographers produced some interesting studies and maps of natural regions bounded by natural features during the period. Hartshorne makes clear that geographers abandoned the notion that geography was solely the study of natural regions, although he argues that this movement was the genesis of modern physical geography.

The concept of natural regions remains part of the discipline of physical geography. In biogeography, natural boundaries delineate major BIOMES: forests, grasslands, deserts, tundra, and marine. In geomorphology, natural boundaries define areas of various types of landforms, including expansive plains, plateaus, and mountainous areas. Natural boundaries define the regional limits of numerous other environmental phenomena; they separate climates, vegetation types, soils, geological formations, environmental classifications, and so on.

Unlike boundaries of a political unit, boundaries of a natural region do not have surveyors' monuments to alert us to their locations. It usually takes an informed observer to identify such boundaries. In addition to geographers, scholars ranging from anthropologists to zoologists, concern themselves with identifying natural boundaries, as they also study plant and wildlife within the confines of natural regions.

A boundary of a natural region is actually a transitional zone that is sometimes difficult to define. For instance, the topographic boundary between the Great Plains and the Rocky Mountains in North America is a gradual change from planar to mountainous terrain. This boundary is an example of a single-feature boundary, as it separates two classes of one element—landforms. Boundaries of multielement regions are more difficult to define, as each element's distribution fails to coincide perfectly with that of the other elements. For example, broadleaf deciduous trees and coniferous trees do not coincide well in a mixed forest biome. As a result, the biome's boundary is a compromise that depends upon the decision of the scientists who are defining the region.

## ORGANIC STATE THEORY

In the late 19th and early 20th centuries, some political geographers treated the state (meaning a country) as if it were a natural region. Friedrich Ratzel was an influential German political geographer who developed this organic state theory. He used an analogy to compare the state with an organism. According to his analogy, a state is a living thing. Like plants and people, it needs living space and resources and constantly competes against other states for them. Hence, state boundaries are natural or organic entities that must grow outward for the state to survive. Strong governments, according to this view, would seek to adjust their natural boundaries by conquest or annexation. Ratzel emphasized that his description was an analogy, not a basis for state policy.

A few scholars of the time—notably the Swedish political scientist Rudolf Kjellén—took Ratzel’s analogy literally and insisted flatly that the interdependence of people and land creates an organic state. This so-called theory, as Kjellén saw it, gave countries a rationale to use force to expand their borders to meet their territorial needs. These ideas later expanded in the 1920s by the German Karl Haushofer. The German dictator Adolf Hitler adopted Haushofer’s organic state theory wholeheartedly. Hitler called his organic state the Fatherland. The Fatherland, according to Hitler, was composed of Germans, who were an advanced “race” of people whose superiority came from an innate spiritual bond with the land. Before the outbreak of World War II, heavy concentrations of Germans lived in countries adjoining GERMANY. Hitler believed that unifying the superior German race would strengthen the Fatherland, which would then continue to grow its boundaries through armed aggression until it encompassed Europe.

Hitler’s persuasive speeches and Nazi propagandists’ deceptive maps seduced German citizens into thinking that expanding Germany’s borders to include other Germans living in adjoining countries was the right thing to do. Hitler began expanding German territory to its “natural” limits by invading Austria in 1934; this was a country composed entirely of German speakers.

Under the same trumped up pretext, Hitler invaded the Rhineland in France (in 1935), annexed part of Czechoslovakia (1938), and invaded western Poland (1939). All these areas had large German populations. The invasion of Poland precipitated World War II, as most countries of Europe knew Hitler’s aggression would not stop in German-populated areas. Italy and

JAPAN subsequently used variations of the facile organic state theory to justify their aggressions as well.)

Geographers are not to blame for World War II; they discarded the organic state theory into the dustbin of bad ideas long before the war began. Rather, the blame goes to self-serving demagogues who resurrected, perverted, and used the theory as a rationale for boundary aggression and war. Lamentably, in a culturally diverse modern world, misguided claims to natural-cultural boundaries are always a danger. For example, Bosnia and Herzegovina’s leaders, whose population is composed mainly of Serbs, used ideas akin to the organic state theory to justify “ethnic cleansing” and forced emigration of non-Serbian minorities in the 1990s. Only military action by U.S. and North Atlantic Treaty Organization forces was able to stop government-sponsored terror in that country.

A lesson from Hitler’s Germany and Bosnia and Herzegovina’s “ethnic cleansing” is that country boundaries are not natural and therefore limited to a particular nation or group of people: Mountains, rivers, lakes, oceans, and cultural lines only become boundaries after people decide that they should be. Indeed, countries have a choice of using fairness and compromise over prejudice and war in dealing with so-called natural boundary disputes.

## boundaries, political

**POLITICAL BOUNDARIES** are frequently defined as borders constructed and imposed on or around a geographic territory in order to distinguish between areas of governance or types (strategies) of political control. They function both as a tool for managing a group of

peoples and as a way of minimizing conflict and organizing efficient political units. Political boundaries can divide not only territory but cultures, languages, ethnicities, and natural resources. In doing so, they can provide people with a sense of security and belonging or, alternatively, with a sense of exclusion.

Political boundaries appear in multiple, differing forms and operate on a variety of scales. The most commonly pictured political boundary is one that takes the form of a man-made physical structure, for example, a barbed-wire fence or a checkpoint. Major international political boundaries frequently take this particular form, particularly political boundaries between uneasy, unstable political neighbors. These political boundaries can often become particularly militarized, as evidenced by the border between the UNITED STATES and MEXICO, although certain international borders lack any means of physical monitoring (certain sections of the border between the United States and CANADA, for example).

Other political boundaries may follow natural, physical boundaries. The edge of a lake or the path of a riverbed can provide a naturally occurring political boundary. Finally, political boundaries can also be visible only on a map and not at all evident to the naked eye. This type of particular border can be found between counties within individual states in the United States, for example. This does not make the border less effective in dividing a particular region or area into political units, but instead suggests that there is no risk to the state in allowing individuals to freely travel between such political units.

Political boundaries occur at a variety of different scales, from global (boundaries between nation-states) to local (boundaries between towns, voting districts, and other municipally based divisions). Such boundaries can also occur at an international level, “above” the nation-state. International boundaries are becoming increasingly important as international human rights takes on an increasingly visible role in the international arena. Such boundaries can include those between organizations providing certain measures of security and countries that are not a part of such a group and not protected by their resources. At all levels, however, political boundaries not only demarcate political control, but determine distribution of resources, from international protection to other, more local benefits, demarcate areas of military control, divide economic markets, and create areas of legal rule.

As a general rule, political boundaries are never static but rather are constantly subject to shifts and

changes. Traditionally, boundaries between countries have received the most attention, and been the subject of the most intense disputes. Such disputes over political boundaries arise over questions involving how to determine where boundaries are located, how such boundaries are to be interpreted, and who should control areas within the boundaries at issue. Efforts to change international political boundaries between nations require consent of the relevant nations; however such borders are more often the site of attempts to forcibly change (or ignore) political boundaries. When such consent is not forthcoming, political boundaries frequently become the site of conflict.

Where political boundaries divide (or combine) ethnic groups, such boundaries can feed ethnic conflict, as a group of peoples is forced apart or merged together. Political boundaries also raise significant issues surrounding immigrant and refugee flows, as regulations and restrictions over admitting or excluding individuals from a particular nation place a country’s political boundary at the center of the debate.

Within the United States, disputes over political boundaries frequently involve issues of race and class, as reflected in the numerous legal disputes over election districts and accusations of gerrymandering. The recent 2003 case of *Georgia v. Ashcroft* dealt with the issue of redistricting, overruling a lower court decision that had determined that the redrawing of election districts in Georgia following the 2000 election was improper in its attempts to spread the black voting population among a greater number of districts in an effort to elect more Democrats into office. The Supreme Court held that lower courts reviewing redistricting cases should consider all relevant factors and not concentrate solely on the issue of whether or not minorities within existing districts are able to elect a minority candidate.

## POSTMODERN DEBATES

Current postmodern debates over political boundaries suggest that rather than bordered nation-states, we are heading toward a more borderless world, with fluid borders and more interdependence among nation-states. Nation-states in the modern world have suffered increasingly not only from external attacks on their political boundaries, but from internal attacks by self-defined political groups. Part of this transition into postmodernism is a shift in our understanding of political boundaries. Traditionally understood as defining the geographic territory of a sovereign, postmodern studies of boundaries speak of areas of jurisdiction,

many of which are no longer place-bound. These theories try to reconcile changing conceptions of political boundaries and nation-states with the idea that for many people, citizenship and identity remains very place-bound and nation-specific.

Contemporary debates also acknowledge the realization that the effects of communities bounded by political boundaries necessarily impact others on the other side of the political boundaries, fueling the debate over the utility and danger of political boundaries. Countries are increasingly conscious of the impact that policy decisions made within their political boundaries will have on those located outside of a country's political boundaries.

Beyond impacting purely theoretical debates, changes in the concepts of political boundaries will increase the organization, use, and influence of structures and organizations, particularly at the global level. The increasing transparency or blurring of political boundaries has led to increased importance being placed on international organizations. This is particularly true with respect to work being done in the areas of human rights and environmental policy, where transnational organizations are one of the key forces leading both global movements.

Other research into issues of the blurring of political boundaries has focused on the impact of political boundaries on the tourism industry. Political boundaries necessarily present an impediment to tourism in certain respects, imposing passport and visa requirements, and in some instances preventing entry for tourists altogether. Countries have in some instances, however, worked together to lessen the administrative costs of maintaining a border and processing tourists, sharing the infrastructure costs of borders.

The increase in immigrant communities is changing the concept of the nation and decreasing the significance of political boundaries. As immigrants form communities, social ties, and networks within new countries, and as they develop resources (economic, political, and social), they are increasingly developing organizations and institutions that operate above political boundaries. Further, in dealing with immigration issues, individual nation-states are reaching across political boundaries, making policy decisions and taking actions that violate the traditional political boundary of the individual nation-state. This can happen, for example, by countries enacting policies that allow for immigration of certain individuals who might be criminalized under their home country's laws. Political scientists and others are just beginning to study the

possible impacts of this new trend of what is being referred to as immigrant-based transnationalism.

Political boundaries have become a source of debate with respect to new technologies and modes of communication as well, particularly issues involving cyberspace jurisdiction and control. As Dan L. Burk notes, "The primary challenge posed by international information exchange is essentially political and caused by the erosion of political boundaries. This increasing porosity of national boundaries has made it difficult for nations to exercise traditional aspects of sovereignty."

Cyberspace communities are forming that do not take the form of traditional communities, possess no political boundaries, and have no traditional forms of political control. Many unanswered questions remain surrounding how such communities should define their boundaries, and how they are to operate within and with respect to such boundaries.

## Bouvet Island

BOUVET ISLAND, a territory of NORWAY, is known as one of the peri-Antarctic islands, small uninhabited rocks and volcanic islands that circle the frozen continent. It was discovered by Jean-Baptiste Charles Bouvet de Lozier, a lieutenant in the French East Indies Company, on New Year's Day, 1739, but not found again until nearly a century later. Located at one of the

most remote spots on the globe, it has rarely been visited and little is known about its landscape. It has been administered by Norway since 1928, which designated it a nature reserve in 1971. Norway also maintains an automated meteorological station.

The island is located about 1,800 mi (2,900 km) north of ANTARCTICA. The island is volcanic and forms the southern terminus of the submarine Mid-Atlantic Ridge. Three volcanic peaks rim an ice-filled plateau (the Wilhelm II Plateau), which is the collapsed center of an older volcano.

Two large glaciers descend from this plateau, sharply on the west, and more gradually on the east. Steep cliffs, up to 1,650 ft (500 m) high, encircle the island and add to its inaccessibility. Most of the island is covered with ice several hundred meters thick. Bouvet de Lozier had originally hoped to find a convenient provisioning spot for French trading vessels but was discouraged by the island's climate.

It was claimed by Britain in 1825 and renamed Liverpool Island. Whalers and seal hunters visited its waters, but this was never a huge industry since the island lies within the Antarctic convergence zone (unlike other islands of the South Atlantic or South Indian oceans) and is therefore trapped by sea ice for much of the year. Since the 1970s, there has been little human activity, with the exception of a mysterious nuclear bomb test to the northeast in 1979, which remains unclaimed (suspicions fell on South Africa).

## Brazil

**Map Page** 1140 **Area** 3,286,488 square mi (8,511,965 square km) **Population** 184,101,109 **Capital** Brasilia **Highest Point** 9,888 ft (3,014 m) **Lowest Point** 0 m **GDP per capita** \$7,600 **Primary Natural Resources** bauxite, gold, iron ore, uranium, petroleum.

BRAZIL IS THE LARGEST and most populous country in South America. The country occupies almost half of the continent. Slightly smaller than the UNITED STATES, it is the fifth-largest country in the world. Brazil has become the leading economic power in South America, due to its vast natural resources, a large labor force, and impressive developments in industry and agriculture. At the same time, income distribution in the country is highly unequal.

The ATLANTIC OCEAN borders Brazil to the east. The country shares a border with every country in South America except for CHILE and ECUADOR. A majority of Brazil is tropical, as it is located between 5 degrees north and 33 degrees south latitude. A small percentage of the country is below the TROPIC OF CAPRICORN.

By the end of the 20th century, the population of Brazil had reached about 180 million. The population has grown extremely fast since 1950, with annual growth rates greater than 2.2 percent. Because of the recent and rapid population growth, Brazil possesses a young population, with two-thirds of the people under age 25. The population is unevenly distributed, as it concentrates along the coast. Coastal areas have a population density of about 12 inhabitants per square mile, while in the interior that figure is a mere 2 people per square mile. Brazil is also a highly urbanized country, with two-thirds of the population living in cities. Population growth has been accompanied by significant rural-to-urban migration.

The population of Brazil is a mixture of Native American, European, African, and Asian peoples. Brazil had no large Native American civilizations as in MEXICO or PERU. At the time of the arrival of Europeans in 1500, there were perhaps 1 million indigenous people in Brazil. These native inhabitants can be divided into two main categories: the Tupí-Guaraní and the Tapuya. In 1500, the Portuguese became the first Europeans to encounter Brazil, which became a Portuguese colony until 1822. In the 19th and 20th centuries, numerous European immigrants came to Brazil from countries such as PORTUGAL and ITALY. Brazil also possesses a large African population as a result of the slave trade. Brazil received more African slaves than any other New World colony. In 1888, Brazil became the last country in the Western Hemisphere to abolish slavery.

The Guyana Highlands in northern Brazil extend into the neighboring countries of VENEZUELA, GUYANA, SURINAME, and FRENCH GUIANA. The region is rugged and transportation is difficult. Many parts are still very inaccessible, and the Guyana Highlands are one of the

world's last natural and cultural preserves. The highest peak in the region is Mount Roraima, which reaches 9,432 ft (2,875 m). While the area is rich in mineral resources, few have been exploited until recently. Some parts of the northern highlands are now heavily mined for gold, diamonds, iron-ore, and bauxite. There are also many rapids and waterfalls in the Guyana Highlands, most of which drain into the AMAZON system.

The Amazon is the dominant river system in Brazil. The river is so large that it is often referred to as the "river-sea" in Portuguese. The Amazon River has a greater volume of water than any river, containing 14 times the volume of the MISSISSIPPI RIVER. The river's width varies from 1.9 to 8.8 mi (3 to 14 km), making it impossible to see from shore to shore at many points. The Amazon begins high in the ANDES mountains in Peru and flows eastward toward the Atlantic Ocean for some 4,000 mi (6,437 km). More than 1,000 tributaries join the river along the way. The Amazon and its tributaries provide more than 25,000 mi (40,233 km) of navigable routes. At 200 mi (322 km) across and 200 ft (61 m) deep, the mouth of the Amazon is so wide that it holds the Ilha de Marajó, an island the size of SWITZERLAND. Ocean-going ships can reach the city of Manaus, located 1,000 mi (1,609 km) inland.

## RAINFOREST

The BASIN around the Amazon River is the largest in the world. It drains some 3 million square miles in Brazil alone and covers more than one-third of the country's territory. The Amazon basin is an ecologically diverse region that includes RAINFORESTS and tropical GRASSLANDS. One-third of the world's rainforest is contained in the Amazon region. The Amazon rainforest possesses a great variety of plants and animals. However, exploitation by human beings has threatened the environment in the Amazon. From a 19th-century rubber boom to 20th-century gold rushes, Brazil has often attempted to exploit the region. The resultant increase in human settlement has led to the destruction of much of the Amazon rain forest.

The Brazilian Highlands, also called the Brazilian Plateau, make up the heart of the country, covering more than one-third of Brazil's territory. The Highlands stretch from the south near the borders with URUGUAY and PARAGUAY to the north near the Amazon River. This region of Brazil is mostly old, eroded landscape that averages 2,000 to 3,000 ft (607 to 914 m) in elevation. The Brazilian Highlands are similar geologically to the Guyana Highlands, with many rapids and waterfalls. The most famous waterfall in the region is

*The Statue of Christ the Redeemer, overlooking the city of Rio de Janeiro, Brazil, is one of the tallest statues in the world.*

Iguaçu Falls. The Iguaçu River consists of miles of rapids, which fall dramatically to join the Paraná River. The Brazilian Highlands can be divided into three subregions: the Great Escarpment, a large interior zone of sedimentary rocks, and the Mato Grosso Plateau.

Located along the Atlantic edge of the Brazilian Plateau is the Serra do Mar, or the Great Escarpment, which provides a barrier between the coast and the interior of the country. The Great Escarpment rises abruptly from the Atlantic Coastal Plain to heights up to 9,000 ft (2,743 m). Because of the presence of the Great Escarpment, few rivers flow from the interior to the coast, with the São Francisco being the major exception. The escarpment has historically served as an obstacle to human settlement in the interior of Brazil. The Atlantic side of the Great Escarpment receives heavy rainfall. The port city of Santos on the coast re-

ceives some 8 in (20 cm) of rain annually. In contrast, São Paulo receives only 50 in (127 cm) per year. Rainfall decreases moving westward. The escarpment and the interior to the west have rich mineral deposits. In the 17th century, colonial Brazil enjoyed a gold and diamond boom. By the 20th century, important industrial minerals such as titanium, manganese, chromium, and tungsten were mined.

The large interior region of the Highland consists of sedimentary rocks over the old crystalline base. In the north is the famous *sertão*, a desolate, eroded backland. Consisting of scrub forests, these backlands receive very irregular rainfall, leading to long droughts and flash floods. In the south is the Paraná Plateau, where deposits of volcanic lava created the famous fertile red soil important for the production of coffee and other agricultural products.

Brazilians have long seen the Mato Grosso Plateau as a frontier area of great potential. Brazil acted on this view by building the new national capital of Brasília there in the 1950s. This new capital in the interior of the country would serve as a symbol of modern Brazil. In later years, the plateau has been opened to mining. Also located in the Brazilian Plateau is the Pontanál, a large wetland drained by tributaries of the Paraguay River. This wetland is home to much biological diversity. However, it is severely threatened by human development.

The Atlantic Ocean has always been important for Brazil. Immigrants, traders, money, and ideas all flowed into the country across the ocean. Brazil's great natural resources flowed out via the Atlantic. The country's population has historically stayed close to the narrow Atlantic Coastal Plain. One 17th-century historian wrote that Brazilians "cling crab-like to the beaches." The coastal plain possesses a number of excellent bays such as Todos os Santos and Guanabara.

The Atlantic Coastal Plain was once covered with dense forest. Even before the arrival of Europeans in the 1500s, the native Tupí people practiced slash-and-burn agriculture that involved clearing much of the forest. The Portuguese continued to destroy much of the forest. Only about 10 percent of the original Atlantic forest remains. The region is home to many rare and endangered species that are found nowhere else in the world.

The plain is widest at the Reconcavo region near the city of Salvador da Bahia. It was here that Portuguese settlers implemented a large-scale system of sugar plantations. Using slaves, the Portuguese made Brazil into the world's leading sugar producer.

## British East India

IT CAN BE ARGUED that Portuguese, Dutch, and French merchants exploited India; Britain remade the subcontinent. British East India grew from a series of coastal trading posts to encompass the part of the Indian subcontinent taken by the current states of INDIA, BANGLADESH, and PAKISTAN. The subcontinent's southern peninsula extends to the HIMALAYAS mountains that separate the subcontinent culturally and geographically from the colder CHINA and MONGOLIA and Asia proper. Bangladesh, India, and Pakistan cover 1.5 million square mi (3,885,820 square km) of land. The climate ranges from tropical monsoon in the south to temperate in the north. Geographical features include the Deccan Plateau, the Baluchistan Plateau, the INDUS and GANGES Plains, as well as mountains and deserts.

The Governor and Company of Merchants of London Trading into the East Indies received its charter from Queen Elizabeth on December 31, 1600. The first East India Company ship reached Surat in 1608, where the company established a factory in 1615. Along India's east and west coasts, English communities were settled in Madras (1639), Bombay (1668) and Calcutta (1698.) The company used alliances and treaties with hundreds of local princes to control more of India while also exploiting the East Indies. Mostly, it left the people to themselves, except when it exploited or mismanaged laborers.

In 1717, the company won exemption from customs duties in Bengal. In 1748, the British defeated the French, removing their last European rival. At the Battle of Plassey (1757), Robert Clive bested the nawab of Bengal and became ruler of India instead of its trading partner. The company mismanaged Bengal, alienating the people. Military expenses became almost overwhelming, so the British government implemented

Lord North's India Bill, the Regulating Act of 1773, which established a British governor-general, the first of whom was Warren Hastings. The company continued to collect revenues, negotiate agreements, and expand its territory. The British took territory they considered poorly ruled. Sometimes a remaining native ruler had a British adviser. Under the practice of lapse, British India acquired all states with no successor on the death of their rulers. British India absorbed Sambalpur (1849), Baghat (1850), Jhansi (1853), Nagpur (1854), and Awadh (1856). Annexation, taxation, and desperation provoked the Sepoy Mutiny of 1857–58.

The wars ended company rule as the British occupied the 750,000 square mi (1,942,481 square km) inherited from the East India Company. By 1900, 100,000 British ruled 250 million Indians. Under the Raj (1858–1954), Queen Victoria promised to work for the welfare of the native people.

The doctrine of lapse ended. The British recognized the princely states, roughly 562 of them with 40 percent of the territory and 20 to 25 percent of the population. In practice, outside British India, the states could not escape British political, cultural, and economic influence.

India received the English educational system, an expansion of its coal and iron mining, and plantations for tea, coffee, and cotton. Metal-plated roads and a hundreds of miles of railway linked the major cities and the coast. Telegraph lines stretched 4,000 miles. Agricultural and social reform occurred as well. Indians became increasingly Anglicized. They joined the civil service and published English-language as well as vernacular journals. Indians also became nationalistic in the 19th century. To ease conflicting Muslim and Hindu nationalisms in the late 19th century, the British wanted to partition Bengal into Muslim east and Hindu west.

British East India expanded by absorption of its neighbors. Border disputes with Burma in 1824, 1852, and 1885 resulted in Britain's taking of upper Burma into the Raj as India beyond the Ganges. Burma became a Crown Colony in 1937 and independent in 1948.

Punjab was a region of interest from the 1830s and eventually became part of India. Indian Ghurkas ruling Nepal fought a war with northwest India (1814–16). They conceded territory and Ghurka troops fought in the British and Indian armies. Bhutan and the East India Company had a treaty of cooperation from 1774. After a war in 1864, Britain had oversight of Bhutan's external affairs. The role was taken first by

British India (1910) then by independent India (1947). Bhutan became independent in 1949.

Overseas service under Great Britain command in World War I increased pressure for more Indian participation, with the Indians always a step ahead of what Britain would grant. Finally, after World War II, British India ended, replaced by independent India and Pakistan in 1947. The transition was violent, with perhaps 500,000 dead, and a migration of 11 million Hindus, Sikhs, and Muslims. And states such as Hyderabad that wanted independence had to choose either India or Pakistan. Hyderabad chose India, as did KASHMIR despite being predominantly Muslim.

Britain gave India its university system and its middle class and elite cultural artifacts such as clubs and gyms. Britain standardized grammar, gave away dictionaries, and provided the printing press, the Kalighat school of painting of the 19th century, and cricket as well as scotch and soda.

For the dams, roads, sanitation, and other infrastructure Britain gave India, in return it imposed laws requiring India to produce plantation crops. British restrictions on Indian manufactures kept the economy dependent. The shift from agriculture for internal consumption increased Indian risks of famine and death. By the 1880s, India took as much as 20 percent of British imports. By 1900, India paid Britain £10 million per year in interest and also paid salaries and pensions for the colonial administrators. India paid well for British improvements.

## British Empire

IN THE 15th and 16th centuries, English trading ships were already sailing to JAPAN via Africa, INDIA, and CHINA, but there was no English sovereignty in these places. The term *empire* then designated the association between England, Scotland, IRELAND, and Wales.

During the 17th and 18th centuries, a network of territories stretching from America to Southeast Asia came under British control. The British Empire had been founded. In spite of the loss of the American colonies in 1783, the 19th century saw the rise of empire as British rule was extended to other regions. Over the next century, weakened by two world wars and changing global economics, Britain forfeited most of its possessions and granted independence to lands that had formed the cornerstone of British prosperity and identity for more than three hundred years.

### 17TH CENTURY

The first attempts at venturing abroad with a view to settlement were made in the 17th century by individuals interested in setting up trading initiatives. The first plantation of this type was established at Jamestown, VIRGINIA, in 1607, led by the Virginia Company of London, created in 1606. The company was dismantled in 1624 and Virginia subsequently became England's first royal colony. Government in the Chesapeake region developed along broadly English lines, with the creation of the office of governor, shires or counties, and parishes with local assemblies and magistrates.

New England was settled in 1620 by a small group of dissenting Protestants, the Puritans. The *Mayflower* reached America in 1620 and her passengers chose Plymouth as the site for the plantation of the settlement. The Massachusetts Bay area was colonized in 1630 by way of the Massachusetts Bay Company, established in 1629. By 1650, new American colonies had been created including, CONNECTICUT, NEW HAMPSHIRE, and RHODE ISLAND.

The mid-Atlantic coast and its HINTERLAND between the Chesapeake region and New England were massively settled from 1660 onward. Conquest of New Amsterdam, renamed New York after the conqueror and proprietor the Duke of York, occurred in 1664 and covered a huge expanse of middle territory. Quakers settled in NEW JERSEY in 1675 and proprietor William Penn founded PENNSYLVANIA in 1682. SOUTH CAROLINA was settled in 1670 and NORTH CAROLINA in 1712. In these colonies, the mode of governance gradually became one of self-rule as the century progressed.

English possessions in the Americas were simultaneously being added to by acquisitions and conquests in the Caribbean. By the 1620s, private investors and rich aristocrats had acquired royal patents. Saint Christopher (SAINT KITTS) was settled in 1624, BARBADOS in 1627, Nevis in 1628, Montserrat and Antigua in

1632. JAMAICA was annexed in 1655 following Oliver Cromwell's Western Design on Spanish Possessions. Demand for cheap labor for work on the plantations rose and indentured English servants flooded to the islands. The alternative source of manpower was slavery. Tobacco, cotton, and sugar were the main exports. Other islands were taken toward the end of the 17th century including SAINT VINCENT, SAINT LUCIA, Tobago, and GRENADA.

British government policy in this period was based on an intention to control trade. In the 1650s, Navigation Acts (initially introduced by Cromwell) ensured that only English ships could import to Britain or Ireland or other English colonies, that all exports from the colonies transit through England, and that preferential import duties be reserved for English sugar.

By the end of the century, the English Caribbean colonies had nevertheless managed to secure self-government. A wealthy planter ruling class had emerged and began to dominate the various assemblies and legislatures.

### HUB OF THE EMPIRE

Thus the "Atlantic system" came into being. The Caribbean colonies constituted the hub of the empire, and the American colonies and the Mother Country, the spokes.

On the other side of the ocean, there was little English interest in the western African coast. Various companies were set up there, flourished for a while, and were replaced by others or independent traders. Land was "leased" to the English by indigenous leaders, so to speak of colonization of western Africa in the 17th century would be premature. These outposts were to later become the British colonies of GAMBIA, SIERRA LEONE, and the Gold Coast.

Further afield in Asia, chartered companies were trading for spices, textiles, and exotic merchandise like Chinese ceramics. The English East India Company was one of these and obtained a royal charter in 1599. English trading posts were established in India (in Gujarat and on the eastern Coromandel Coast and later Bengal) with the local rulers' assent. There Englishmen, like traders of other nationalities, "settled" in small communities, notably in Surat and Madras. The English Crown acquired Bombay from the Portuguese in 1661 and as the years passed, white settlement increased around Bombay, Madras, and later Calcutta in Bengal (1690 onward).

These settlements took the shape of forts protected by small contingents of soldiers. In INDIA and Africa,

these settlements were administered by the Companies themselves with a view to protecting trade interests.

## 18TH CENTURY

At the end of the 17th century, English possessions in North America included New England, the Middle Colonies, Virginia, and the Carolinas. Britain acquired Acadia (Nova Scotia), Newfoundland, and Hudson Bay in 1713 thanks to the Treaty of Utrecht. In the south, GEORGIA was settled in 1733 by charter and became a royal colony in 1751. The PENNSYLVANIA frontiers expanded westward and southwestward. Britain had acquired new markets and exports rose significantly in the 1740s. After the Seven Years' War against France (1756–63), Britain made huge gains, including the Floridas and in the north, Quebec. In 1791, Quebec was split into two and Upper Canada became English speaking and Lower Canada became home to the conquered French.

Britain, though, was soon to lose the oldest and most significant part of its recently extended empire. After 1763, the British government made inroads into colony governance in order to reduce expenditure, shore up domestic finances (in a sorry state after the war), and consolidate imperial authority through taxation and strict regulation of trade. These measures worried local American elites used to autonomy.

Confrontations between the “Americans” and the British army began in 1775. The colonies declared their independence in 1776 after a year of fighting. The war lasted until 1783, when a peace treaty was signed. The UNITED STATES acquired territory stretching from the MISSISSIPPI RIVER to the southern shores of the Great Lakes. In terms of empire, Britain was left with British North America, namely the Canadas, Nova Scotia, the Hudson's Bay Company territory, and the Newfoundland fisheries.

The Caribbean, on the other hand, prospered in the 18th century in spite of periodic recession. After the Seven Years' War, the islands under British control were Jamaica, Antigua, Saint Kitts, Nevis, Montserrat, the BAHAMAS, the Virgin Islands, DOMINICA, Saint Vincent, Grenada, and Tobago. After the Napoleonic wars (1793–1815), Britain acquired Trinidad, Saint Lucia, and Demerara.

Britain had also gained prominence elsewhere in the 18th century. In 1744, hostilities at sea between the East India Company and the French were transferred to land in southeastern India as each country allied with contending Indian groups. The British (represented by the company) and the nawabs claimed vic-

tory in 1746. Ten years later, the company and the nawabs were themselves at war. Calcutta was taken but recovered in 1757. Thus, Bengal became a client state and later in 1765 a province under British government rule. Meanwhile, Surat was captured by the British in 1759.

The British government, though, did not actively participate in expanding the Empire in India other than by providing the company with troops. But India did become essential to national prosperity as exports increased. This in turn encouraged greater governmental commitment to conquest. A governor-general was appointed and exercised authority over all the company's territories and a supreme court was set up in Bengal in the early 1770s.

British territorial acquisition was also being consolidated in the south. James Cook's voyages to the Pacific (1768–79) increased British possessions with the discovery of HAWAII, FRENCH POLYNESIA, New Caledonia, NEW ZEALAND and the eastern Australian coast. A penal colony was established in New South Wales in 1788. Meanwhile, at home in Europe, Britain had acquired GIBRALTAR, the gate to the Mediterranean, in 1713 thanks to the Treaty of Utrecht.

The 18th century thus saw the fall of the first empire and the rise of the second. Modes of governance varied. In the West Indies, the system of local self-rule with the governor/elected assembly duo persisted. Nevertheless, in territories that had not been settled by the English (India) and in newly conquered colonies (Trinidad, MAURITIUS, SOUTH AFRICA), Crown Colony government came into effect. This meant that the governor-general was all-powerful and advised by a nominated council.

## 19TH CENTURY

The 19th century witnessed the development of British North America. By 1815, the British North American colonies were Nova Scotia, New Brunswick, Prince Edward Island, Newfoundland, and Upper and Lower Canada. The sparsely settled northwest areas were Hudson's Bay Company territory. British Columbia was created in 1858 once gold was discovered.

After rebellions in these colonies in 1837 and 1838, military governorship was replaced by civil administration. In 1867, Ontario, the Canadas, New Brunswick, and Nova Scotia confederated, thus becoming the first ever Dominion. A central government was formed, based in Ottawa. By 1873, Canada had expanded across the continent, though it remained low on the list of imperial priorities.

The British Empire in the 19th century was just as firmly rooted in the Caribbean as ever before. The West Indian islands under British control were either self-governing or Crown colonies but all still slave societies, with the number of blacks largely outnumbering the whites. In 1823, the Anti-Slavery Society was established to improve the lot of the slave population. Slave rebellions had become frequent in the colonies in the opening decades of the 19th century. Slaves in the British West Indies were finally freed in July 1834 and the apprenticeship system was introduced. But it failed and labor became scarce.

In the 1840s, LONDON, realizing how important it was to keep the plantations profitable, thus effected a reversal in the policy that had previously favored the ex-slaves. Duties on necessities and restriction on franchise qualifications were some of these measures. Indentured labor from other British colonies (India) was recruited to parry the attacks on British prosperity at home and in the Caribbean.

The black populations were increasingly disadvantaged; disease, death, riots, and rebellions became common. The Morant Bay rebellion in 1865 in Jamaica was one of the bloodiest uprisings of the century. As a result, Crown Colony government gradually became the preferred mode of governance in the British West Indies by the 1870s (Barbados, the Bahamas and British Guiana retained self-government) and remained more or less so until after World War I. But this did not put an end to the riots, and with recession, protest swelled as the 20th century dawned.

### AFRICAN EXPANSION

The 19th century was also a time of great expansion on the African continent. Britain had occupied the previously Dutch Cape of Good Hope in 1795. The Great Trek (1834–40) was an attempt on the part of the Afrikaners to leave the British behind and establish their own independent republics further inland. Britain annexed Dutch Natal in 1843. Self-government (involving whites only) was introduced in 1856. Transvaal was annexed in 1877. The Boers rebelled in 1880 and managed to regain almost total control of Transvaal in 1881. Zululand was annexed in 1887.

Representative government was introduced in 1893 as a result of the growing prosperity and industrialization (thanks to diamonds and gold discovered in the Transvaal) of the colonies. Britain became interested in acquiring northern territories perhaps equally rich in gold or minerals. Thus, Nyasaland (later MALAWI) became a protectorate in 1891 and North and

South Rhodesia (later ZAMBIA and ZIMBABWE) became British South African Company territory (a company founded by Cecil Rhodes). Three territories (*swaziland*, Basutoland (later LESOTHO) and Bechuanaland (later BOTSWANA) were known as the High Commission Territories.

Continuing conflicts with the Boer states convinced Britain that its presence in Africa had to be consolidated in the interests of global imperial influence. In 1899, Britain went to war with the Boer states (Transvaal and the Orange Free State) with this in mind. In 1900 both Transvaal and the Orange Free State were annexed. A peace treaty was signed in 1902. The South African colonies united in 1909.

As far as West Africa was concerned, by the end of the 19th century Britain had occupied the Gambia, Sierra Leone, the Gold Coast and NIGERIA. Trade increased, as did the infrastructure necessary to its development (railways, roads, and mining technology). White settlement, though, remained sparse, and policy was based on development by native populations and governance by local African rulers.

### THE ASIAN EMPIRE

Asia also became one of the prime sites of the growing power, force, and influence of Britain. Dutch colonies, namely SUMATRA, Malacca, Ambon, and Banda, were occupied by the Anglo-Indians with the assent of the exiled King William V at the end of the 18th century (1795). Britain acquired SINGAPORE in 1819 after intervention in internal politics. HONG KONG was acquired by cession in 1842 and returned to China in 1997. British India declared war on Burma in 1824 which culminated in the acquisition of Assam. By 1885, after three wars, the whole of Burma was British.

Toward the end of the 18th century, metropolitan intervention in India had taken many forms including the creation of the office of governor-general, the law courts, and the Indian Civil Service. The conquest ethos of the company was nevertheless alive and well and underpinned by the Royal Navy and the company's land armies. Sind was conquered in 1843 and the Punjab in 1849.

Governance in these acquired territories became rooted in the military even after the company lost its monopoly in India and China in 1813 and 1833. Native populations were paying the price, and discontent came to a head in 1857 with the Great Mutiny and Civil Rebellion. In 1858, the company was abolished and India became a Crown Colony under the direct rule of a secretary of state and the Council of India.

Over the next half century, British administrators ruled India hand in hand with the British army and Indian forces. Members of the Indian middle class were given the opportunity to become civil servants and so to participate in the administration of British India (their lower salaries also allowed for savings for the British government). The Indian National Congress was formed in 1885 and was a means of expressing claims for greater representation, demands that were partially satisfied in 1892.

In 1906, the All India Muslim League was formed to parallel the Hindu-dominated Congress. By 1909, Indians were present in the various executives. The move toward a federal system of government for India (with self-governing provinces and a central imperial government) was supported by Lord Crewe (secretary of state) and endorsed by the king. Further south, Ceylon (SRI LANKA) became a British Crown Colony in 1802. In the early 20th century, Ceylon began its campaign for independence which it obtained in 1948.

### PACIFIC EXPANSION

The empire was equally active and territorially expanding in the Pacific. The 19th century witnessed the transformation of a struggling penal settlement established in 1788 into a group of six self-governing and prosperous colonies (New South Wales, Victoria, Queensland, Western Australia, South Australia and Tasmania). AUSTRALIA was dependent on the Mother Country for defense purposes and returned the compliment whenever the empire required help in wars against for example, the Maori in New Zealand (1860s) or in South Africa (1899). This did not, however, prevent leanings toward independence at the end of the century. Federation came in 1901 but did not mean the complete severing of ties with Britain. British control of New Zealand was overseen by Sydney, but the territory was formally annexed by Britain in 1840. The Treaty of Waitangi, signed in 1842, laid out how colonization would proceed.

New Zealand became a Crown Colony but quickly progressed to a more democratic form of government in 1846, when assemblies were introduced. Maori challenge to British sovereignty came in 1863 with the Waikato war. The Maori were forced to retreat after a year's fighting. New Zealand acquired greater self-government in 1864. At the end of the 19th century, New Zealand had acquired Dominion status.

British possession of the Pacific islands was based on a policy of supporting existing native power bases and also meant the development of trade (whaling,

sandalwood). The Pacific islands under British control at the end of the 19th century were FIJI (1875), the SOLOMON ISLANDS (1893), the Cook Islands (1888), TONGA, PITCAIRN, and New Guinea (1884). The New Hebrides were under French and British control from 1906 onward. These islands, though, did not benefit from any concerted imperial effort in development or investment. French Polynesia, a British possession was annexed by the French in 1842 and New Caledonia in 1852.

At home in the Mediterranean, MALTA became a British possession after the Battle of Waterloo in 1815. CYPRUS was taken in 1878 and Britain occupied EGYPT in 1882 with the ruling khedive's assent. This state of affairs was a result of Britain's desire to control the Suez Canal (opened in 1869) and to protect trade interests. Britain declared Egypt a protectorate in 1914.

### 20TH CENTURY

At the dawn of the 20th century, the British Empire was extensive and prosperous, but changes were in the offing.

In India, reforms in 1919 and 1935 meant that Indians had acquired more decision-making power, though this did not mean that the two groups were on an equal footing, as the British diligently maintained their separateness. The Indian National Congress had become a more organized political party, acquiring more and more weight thanks to electoral successes.

The issue of imperial domination and Indian nationalism was articulated in various ways until Gandhi's policy of passive resistance (noncooperation and civil disobedience) united the Indians. World War II pushed Britain to propose in 1942 full Dominion status or secession in exchange for India's support. India refused and Gandhi's civil disobedience movement continued. The offer was renewed after the war as Britain was eager now to divest itself of the responsibility of maintaining British rule in India. Interest in the area (employment opportunities for the British, source of indentured labor for other colonies, strategic interest, source of trade, investment, and remittances) had started to wane by the 1930s. This was brought on by shifts in global economics as well as Britain's own reforms and finances.

Tensions between the Muslims and the Hindus concerning the shape of the new nation to come flared into violent encounters. Some British officials argued for a quick exit and partition. A separate Muslim state (PAKISTAN) was created, thus leaving the Indian National Congress with a secular state in 1947. India be-

*The British Empire as it appeared in 1930 still held numerous colonies and possessions around the world. The axiom “the sun never sets on the British Empire” was true before World War II.*

came a member of the new Commonwealth of Nations (1949), made up of the Dominions and the newly independent ex-colonies. This was the end of British rule in India and the beginning of a general move toward decolonization all over the empire that occurred over the next few decades.

In the Caribbean, the racist treatment of West Indian soldiers in wartime led (once they returned home) to a growing feeling of discontent with imperial domination. Strikes and protests by workers added to the rising dissatisfaction. By the 1960s, the British West Indies had acquired self-government. Most islands became independent in the 1960s and 1970s. The TURKS AND CAICOS ISLANDS, the CAYMAN ISLANDS, Montserrat, and the British Virgin Islands chose to remain colonies.

Similarly, in Southeast Asia, nationalism started to stir in the interwar period, but as in India, resistance to the empire was not the sole reason for British concessions. Britain’s incapacity to continue to defend its ex-

tensive empire became apparent as World War II was being fought. Burma gained independence in 1948 and did not join the Commonwealth. MALAYA became independent in 1957 and did. Malaysia (Malaya, Singapore, Sarawak, North Borneo) was created in 1961–63. Singapore, though, seceded from Malaysia in 1963. As a result of international movements, nationalist demands, and a lack of British funds and commitment, the empire in Southeast Asia was at an end.

The beginning of the 20th century witnessed the opening up of the interior in British West Africa (Gambia, Sierra Leone, the Gold Coast and Nigeria). Gold and tin became major exports from British West Africa. The British were in ultimate control even though a system of indirect rule was in effect. In the 1920s, the National Congress of West Africa was formed and formulated demands for better representation. As during World War I, British West Africa contributed to the second war effort, and when it ended,

access for Africans to the higher echelons of colonial government became easier. Reforms for representative government were introduced. The Gold Coast (GHANA) became independent in 1957, Nigeria in 1960, Sierra Leone in 1961 and Gambia followed in 1965, all becoming members of the British Commonwealth of Nations.

SOUTH AFRICA became a Dominion in 1909 and its sovereign status (like that of Canada, New Zealand and Australia) was acknowledged in the 1931 Statute of Westminster, which put the Dominions on a par with Britain. South Africa gradually became one of the richest countries in Africa, building its wealth on mining, cheap black labor, and discriminatory racist policy. The African National Congress was formed in South Africa in 1912 in response to the situation. In 1961, in the face of British condemnation of such policies, South Africa became a republic and left the Commonwealth.

Britain's domination of East Africa had been formalized in 1890 with the creation of a protectorate over what was then Buganda (UGANDA), KENYA, and TANGANYIKA. Zanzibar was annexed in 1896. The politics of identity became relevant in the 1920s in the East African colonies. Independence came to Tanganyika (TANZANIA) in 1961, to Uganda in 1962, and to Kenya in 1963.

The High Commission Territories of Swaziland (1968), Basutoland (1965), and Bechuanaland (1966) gained independence in 1960s. In North and South Rhodesia, the white population voted for self-government in 1923 when the company charter came to an end. North and South Rhodesia and Nyasaland federated in 1953 and became the Central African Federation.

The federation did little to better the situation of blacks in spite of economic growth. This obviously led to protest and the rise of nationalism. In 1964, Nyasaland (Malawi) and North Rhodesia (Zambia) became independent. White colonists in South Rhodesia illegally claimed independence in 1969, and the blacks gained control of their country, Zimbabwe, in 1980, which meant the close of the British Empire in Central Africa.

On the other side of the Atlantic, Canada became economically closer to the United States. Newfoundland, which had not been a part of the confederation, had acquired Dominion status in 1931 but relinquished government to Britain in 1933 as a result of economic difficulties. After a referendum in 1949, Newfoundland became a Canadian province. Cana-

dian citizenship was introduced in 1947 and British imperial referents slowly disappeared.

At the turn of the century, Australia and New Zealand were also both Dominions. Australia adopted the Westminster Statute in 1942 and New Zealand in 1947 (Canada in 1931). Both countries passed Constitution Acts in 1986, which severed the final links with Great Britain (though the queen is still head of state in all three countries). The Pacific Islands won independence between 1960 and 1980. Western Samoa was granted independence by New Zealand in 1962, the Cook Islands chose self-government in association with New Zealand in 1965, NAURU became a republic in 1968. Fiji acquired independence in 1970, PAPUA NEW GUINEA in 1975, Tonga in 1970, the Solomons in 1978, and VANUATU (New Hebrides) in 1980.

In the Middle East in 1936, Egypt and Britain signed a treaty that stipulated the withdrawal of the British from the cities but provided for the concentration of troops in the Suez zone. In 1954, the British agreed to withdraw from the canal. Aden was relinquished in 1967 and Great Britain withdrew from the Gulf in 1971 after the creation of the UNITED ARAB EMIRATES.

By the 1980s, Britain had relatively peacefully parted with almost all of its possessions. Today, the Commonwealth of Nations groups large and small ex-colonies in a network of free association. This active international organization is a legacy that attests to the bygone economic power and global spread of what used to be known as the British Empire.

## British Indian Ocean Territory

THE BRITISH Indian Ocean Territory (BIOT) is an archipelago in the INDIAN OCEAN, south of INDIA, about one-half of the way from Africa to INDONESIA. On No-

vember 8, 1965, the British government created the (BIOT). The BIOT consisted of the Chagos Archipelago, excised from the British Crown Colony of Mauritius; and the Aldabra and Farquhar islands and Île Desroches, excised from the British Crown Colony of the Seychelles. Both MAURITIUS and the SEYCHELLES later claimed that these actions were in contravention to the United Nations declaration on the granting of independence to colonial countries. Approximately 1,200 residents of the islands, living as agricultural workers, were relocated by the British government to Mauritius and the Seychelles. Upon independence from Britain in 1968, Mauritius made immediate claim to the Chagos Archipelago and requested the resettlement of all indigenous populations. Subsequently, Britain transferred a number of the BIOT islands to the Seychelles when it attained independence in 1976. BIOT now consists of the six main island groups comprising the Chagos Archipelago.

The largest island of the Chagos Archipelago is Diego Garcia, reportedly named by Portuguese explorers in the 1500s. Portugal's claim lapsed and in the early 1700s the French claimed the islands. They administered them from Mauritius and eventually established copra plantations with slave labor. Britain obtained these islands along with several French claims in 1814. Britain leased the island of Diego Garcia to the UNITED STATES in 1966. The lease is for a 50-year period until 2016, with a 20-year extension available if both parties agree to continuation.

In 1971, the United States began to transform Diego Garcia into a naval support facility that soon included deepwater docks and an expanded runway. In the 1980s, the United States increased its presence on Diego Garcia by building new airfield facilities, and an air force satellite detection and tracking station, initiating long-range bomber operations, improving navigational aids, and increasing the port capabilities. The United States maintains a large amount of ground combat equipment on maritime prepositioning ships (MPSs) stationed in Diego Garcia. The United States has built an extensive military support complex that is operated jointly with the British. The facility and its capabilities are operationally invaluable to the U.S. military doctrine of global force projection and its current military operations in the MIDDLE EAST, South Asia, and throughout the INDIAN OCEAN.

Diego Garcia is a coral atoll with a near continuous land rim of approximately 40 mi (60 km). The Chagos Archipelago is made up of some 50 sand cays scattered along a large shoal area known as the Great Chagos

Bank. The whole feature covers some 22,000 square mi (56,995 square km) of the Indian Ocean. A wet tropical climate characterizes the area. Diego Garcia is a near pristine coral atoll ECOSYSTEM.

## Brunei

**Map Page** 1124 **Area** 2,055 square mi (5,770 square km) **Population** 358,098 **Capital** Bandar Seri Begawan **Highest Point** Bukit Pagon 6,105 ft (1,850 m) **Lowest Point** 0 m **GDP per capita** \$18,600 **Primary Natural Resources** petroleum, natural gas.

THE SULTANATE of Brunei is one of the world's smallest countries, but also one of the world's richest. A major landpower in the 15th century, the territory ruled directly by the sultan is now smaller than LUXEMBOURG, but its economic impact in the region is far greater due to the blessings of abundant petroleum and natural gas reserves. Its full name, Brunei Darussalam, is a compound of a Sanskrit name (possibly meaning "sea people" or the name of a local tree that also gave its name to the entire island of Borneo), plus the Arabic for "abode of peace," added to the name by Muslim sultans in the 15th century.

Brunei is one of the four political components that make up the island of Borneo, along with Kalimantan (part of INDONESIA), and Sabah and Sarawak, two states of the federation of MALAYSIA. Sarawak surrounds Brunei and in fact divides it into two pieces. Sabah, Sarawak, and Brunei were at one time all component parts of the British East Indies colonies, but Brunei declined to join the Malay federation in 1961 and remained a British protectorate until 1984, preferring to rely on its own natural resources.

These resources, in combination with a relatively small population, make Brunei's per capita income one

of the highest in the developing world. The sultanate has been ruled by the same family for six centuries, and the sultan is considered one of the richest individuals in the world: It is said he earns \$100 per minute from oil. Brunei's oil production is estimated at 163,000 barrels a day; its output of liquefied natural gas is the fourth largest in the world.

The country consists of a flat coastal plain along the South China Sea in the western part of the country, with some hills further inland. Mountains rise in the eastern segment of Brunei, which is also the most undeveloped and inaccessible part of the sultanate. An equatorial climate gives the area abundant rainfall, and most of the country remains heavily forested, with mangrove swamps along the coast. Most of the people live in the capital of Bandar Seri Begawan, along with its chief port of Maura, 25 mi (41 km) to the northeast.

The other major town is Seria, the center of the oil and gas industry, in the western part of the country. Bandar includes great contrasts, between the sultan's palace and the glittering Sultan Omar Ali Saifuddin Mosque and the world's largest stilt village, Kampung Ayer. This village, in existence for 400 years and providing housing for about 30,000 people, was declared a national monument in 1987 and is the most popular tourist attraction in the country.

His Majesty Sultan Haji Hassanal Bolkiah Muiz'zaddin Waddaulah, the Sultan and Yang Dipertuan of Brunei Darussalam, leads a relatively extravagant life, but is generally ignored by the religiously conservative Islamic population. The sultan is the sovereign in more than just name: Elections have been suspended since 1962, and there is little sense of change in the near future.

At its height in the 15th century, the sultanate controlled the entire north and west coast of Borneo, plus the Sulu archipelago (now in the Philippines). After its first encounter with European colonial powers—it was briefly occupied in 1580 by Spain—Brunei entered a long period of decline, and by the 18th century was a principal center for piracy and slave trade. Labuan, an island commanding the entrance to Brunei Bay, was ceded to Great Britain in 1846 chiefly to protect against this, and by 1888 the entire state was a British protectorate. Economically, Brunei was known only for its exports of gambier, a dye produced from mangrove trees used in dying of leather.

Then, in the early 20th century, large oil reserves were discovered, first onshore in the region of Seria and Kuala Belait, but mostly offshore by the 1990s. The British Malayan Petroleum Company was the

greatest producer of crude oil of any British colony in the post-World War II era, but it is Royal Dutch Shell that has become the major company involved in Brunei's oil industry. Revenues derived from this company alone have been significant in what is sometimes called the "Shellfare State," in which all local residents enjoy free education, health care, and no taxation. Local residents (mostly of Malayan extraction) are less willing to work in industry, so there is a sizable immigrant community of Filipinos and Thais. Oil reserves are expected to last 40 years, but the sultan's government is already implementing a National Development Plan to reduce Brunei's dependence on oil-based industries; \$7.2 billion has reputedly been allocated for this plan, investing in production of rice, fruit, fisheries, and livestock—in 1981 the government purchased a cattle ranch in northern Australia that is larger than the entire country—with an equal push to boost tourism.

## Buenos Aires

BUENOS AIRES IS the largest city in ARGENTINA, and as part of a federal district, it serves as the country's capital. The city's name means "good airs" and derives from the name of a patron saint of navigators known as Nuestra Señora Santa María del Buen Aire. Measuring 77 square mi (199 square km), the city is located in eastern Argentina, near the South ATLANTIC OCEAN, just south of Argentina's border with URUGUAY.

In 1536, the Spanish explorer Pedro de Mendoza led an expedition that founded the city of Buenos Aires on the banks of the Río de la Plata. This initial settlement failed after five years because of a lack of supplies and conflicts with the native inhabitants. The Spanish settlers fled Buenos Aires for the fortified city of Asunción. In 1580, Juan de Garay led a new expedition from Asunción that reestablished Buenos Aires. The new settlers began to exploit the pastoral animals that had multiplied since being left by the earlier settlers.

For more than 200 years, Buenos Aires grew slowly. While the city possessed a good port, it was

largely excluded from the highly regulated Spanish colonial system of trade. Spain permitted only trade through certain ports in the New World and in SPAIN. As a part of the Viceroyalty of Peru, Buenos Aires was governed from Lima and its port of Callao. Thus, to obtain European goods, *porteños*, as residents of Buenos Aires are known, had to wait for them to be shipped through Callao and then by oxcart to Buenos Aires, which could take six months. To export their goods, residents of Buenos Aires also had to ship them through Callao and then to Spain.

Before the second half of the 18th century, Buenos Aires had little contact with the silver mining regions of the viceroyalty. Instead it developed an economy based on ranching and contraband trade. This contraband trade, especially with Brazil and the Caribbean islands, allowed *porteños* to thrive. In 1618, the city became the seat of an imperial governorship. By the 18th century, they were exporting cereals, hides, and dried beef. By the mid-1700s, the city's population had reached 20,000. In 1776, as part of a series of reforms implemented by the Spanish government, Buenos Aires became the capital of the new Viceroyalty of the Río de la Plata. The city now had administrative authority over much of southern South America. With its new status, legal trade greatly expanded and Buenos Aires prospered from direct trade with Spain and with the mining regions of South America. Economic prosperity also led to increased population, which reached 42,500 in 1810.

In 1806 and 1807, British forces attacked the city. Local militias succeeded in repelling the attackers, contributing to the *porteños'* sense of pride and nationalism. In 1808, city residents opposed Napoleon's invasion of Spain, and in 1810, the town council cut its formal ties with Spain, replacing the Spanish viceroy with a colonial-dominated junta. For the next decade, the city was a center of revolutionary activity. However, the interior provinces did not immediately follow the lead of Buenos Aires. Finally, in 1816, the provinces also declared their independence and Buenos Aires became the capital of the newly independent United Provinces of the Río de la Plata. Much of the first half of the century was marked by political and military conflict between *unitarios* and *federales*. The *unitarios* were those who favored a strong central government at Buenos Aires, while the *federales* preferred provincial autonomy. Buenos Aires generally dominated the struggle. In 1880, the city separated from the province of Buenos Aires and became Argentina's national capital as part of a federal district.

In the second half of the 19th century, Buenos Aires prospered and grew. By 1860, the city had more than 100,000 residents, and by the early 20th century, the population had surpassed one million. Several factors contributed to the transformation of the city, all of which were reflections of the economic prosperity of the surrounding countryside.

One change was the arrival of massive numbers of immigrants from Europe and elsewhere. About 80 percent of the immigrants came from Spain and ITALY. By 1914, half of the city's population was foreign born. Often unable to buy land in the countryside, many immigrants settled in Buenos Aires, as there was a need for labor in the city's port, industries, and service sectors. Many older sections of the city came to be dominated by foreigners.

A second change was the flow of wealth into the city. This wealth can be seen in the construction of numerous great mansions in the city. Indeed, Buenos Aires came to be a symbol of great wealth and the phrase "to be rich as an Argentine" could be heard on the streets of Paris. A third change was the spatial change that took place. Buenos Aires sought to copy the model of PARIS, especially as it began to prepare for its centennial celebration in 1910. Thus, the city constructed a subway system and broad avenues like those in the French capital. Other improvements included sanitation, gas, electricity, and water.

By 1914, Buenos Aires had reached a population of over 1.5 million, making it one of the 10 largest cities in the world. About one-fourth of Argentina's entire population lived in the Buenos Aires metropolitan area, which was seven times larger than the second biggest city in the country. Several key developments marked the 20th century.

First was a change in the source of newcomers to the city. After about 1930, European immigration virtually ended. Migrants from the interior provinces of Argentina filled the city's labor demands. Others came from the neighboring countries of Uruguay, PARAGUAY, and BOLIVIA. Most of the new arrivals were mestizos. This racial difference led to frequent social conflict. Most of the migrants were poorly educated and had few job skills, making it difficult for the urban economy to employ them. Many of these migrants became supporters of Juan Peron, often viewed as the champion of the poor.

A second, related, change was growing urban poverty. Despite the support of politicians such as Juan Perón, the new migrants remained poor. Most found the inner city too crowded. Instead, they chose to live

in the growing shantytowns that surrounded Buenos Aires, known as *villas miserias*.

A third key development in the 20th century was a change in urban transportation. Like many other modern cities, Buenos Aires came to be dominated by automobiles and buses, replacing the electric streetcar system. However, Buenos Aires lacks a major freeway system. A network was planned after World War II, but it was never built. The building of the Metropolitan Railroad in 1979 helped somewhat. However, by the end of the 20th century, traffic problems and urban gridlock were commonplace in the Argentine capital.

A final development was industrialization. In 1914, the city had 17,000 industrial establishments that employed some 300,000 people. By the 1960s, there were more than 70,000 establishments providing jobs to more than 700,000 *porteños*. Some 40 percent of all Argentine industry was located in the city. Such industrialization reinforced the flow of migrants to the city. By the end of the 20th century, the metropolitan area had more than 11 million inhabitants, making it one of the largest cities in the world.

## Bulgaria

**Map Page** 1133 **Area** 42,900 square mi (111,910 square km) **Population** 7,537,929 (2004) **Capital** Sofia **Highest Point** 9,596 ft (2,925 m) **Lowest Point** 0 m **GDP per capita** \$7,600 **Primary Natural Resources** bauxite, coal, copper, lead, timber.

BULGARIA IS ONE OF 10 countries in the Balkan Peninsula in southeastern Europe. The peninsula is a mountainous region with river systems flowing in all directions. As a land bridge between Europe and Asia, the Balkans witnessed a long history of warfare and territorial struggle. A number of conquerors in past centuries have exercised control over the region. Once a Roman province, the Balkans later became part of the Byzantine Empire, and still later came under the control of the Ottoman Turks. Bulgaria, formally named the Republic of Bulgaria and known as the People's Republic of Bulgaria when the Soviet Union dominated Eastern Europe (1946–90), is a heavily mountainous country, with its eastern border on the BLACK SEA, and is bounded on the north by ROMANIA, on the west by SERBIA AND MONTENEGRO (formerly the Federal Republic of Yugoslavia), and on the south by TURKEY and GREECE.

Bulgaria has a significant agricultural base in addition to a varied array of mineral resources from mining. Both industrial and agricultural activity increased dramatically during the time Bulgaria was a satellite of the Soviet Union. Two of the leading industrial centers are Varna and Burgas, both on the Black Sea coast. With the rise of industry, Bulgaria has experienced its share of environmental degradation. Rivers are polluted from the discharge of heavy metals, nitrates, and other industrial wastes, as well as raw sewage in some regions. Air pollution from industrial discharges and automobile exhausts has contributed to the presence of acid rain and subsequent widespread deforestation. The country is working to alleviate these environmental problems in part from funds received in the 1990s from the European Community.

A 2004 program has the Danube Regional Project working in close partnership with the International Commission for the Protection of the Danube River on identifying and remedying environmental problems in that world-famous river. The work by these organizations, is expected to expand to Romania, CROATIA, Serbia and Montenegro, and BOSNIA AND HERZEGOVINA, all of which are, along with Bulgaria, in the DANUBE RIVER basin. Bulgaria signed the Kyoto Protocol and is a member country of a number of other international environmental agreements. Bulgaria joined the NORTH ATLANTIC TREATY ORGANIZATION (NATO) and is expected to become a member of the EUROPEAN UNION (EU).

The population of Bulgaria reached its highest total in the mid-1980s at nearly 9 million. Since that time, the population has steadily decreased due to the emigration of large numbers of Turks and ethnic Bulgari-

ans and several years in which the death rate has surpassed the birth rate. Estimates for mid-2004 indicate a birth rate in Bulgaria of 9 per 1,000 people in the country and a death rate of 15 per 1,000. Bulgaria's rate of natural increase (the difference between birth and death rates) in percentage form is -0.6. Recent estimates of regional and country populations for 2050 suggest that Bulgaria will experience the highest percentage loss of any country in the world. Its total population in that year is predicted to be approximately 5 million, a 44 percent decline from its high point of 9 million in the mid-1980s. In fact, all of the countries in Eastern Europe are predicted to decline in population by 2050, and the whole of Europe's population will drop from 728 million in 2004 to 668 million in 2050. All other major world regions are expected to increase in population over this same period.

## Burkina Faso

**Map Page** 1113 **Area** 105,840 square mi (274,200 square km) **Population** 13,228,460 (2003) **Capital** Ouagadougou **Highest Point** 2,457 ft (749 m) **Lowest Point** 656 ft (200 m) **GDP per capita** \$1,100 **Primary Natural Resources** manganese, limestone.

A **LANDLOCKED** republic located in West Africa, bordering GHANA, CÔTE D'IVOIRE, and TOGO to the south, BENIN to the southeast, NIGER to the east, and MALI to the north and west. In addition to the capital, Ouagadougou, major cities include Bobo-Dioulasso, Koudougou, Kaya, and Ouahigouya. The country's terrain is largely semidesert, with less than 10 percent of the land arable without IRRIGATION.

The country has several unnavigable rivers: the Komoé (Comoé) River, which flows through Côte

d'Ivoire; and the Mouhon (Black Volta), Nazinon, and Nakambe (White Volta) rivers, which join in Ghana to form the Volta. The country's predominantly rural population is split nearly in half in terms of religion, with 50 percent of the population practicing Islam, 40 percent practicing indigenous faiths, and the remaining 10 percent Christianity, mostly Catholicism. There are at least 50 recognized ethnic groups in Burkina Faso, dominated by the Mossi, who make up 40 percent of the population. The remainder of the population is distributed among the Gurunsi, Senufo, Lobi, Bobo, Mande, Fulani, and numerous smaller ethnic groups. French is the country's official language, though Oyula is also spoken.

While Burkina Faso has considerable mineral resources, the country remains one of the poorest in the world. Agriculture is difficult, as most of the land is untenable, and drought has prevented major irrigation projects from being undertaken. Because of the lack of agriculture, Burkina Faso must import most of its food, which contributes significantly to the country's increasing debt.

In the 12th century, most of the territory in the western part of Burkina Faso was seized by the Mossi. The states of Ougadougou, Tengkodogo, Yatenga, and Gourma in the east remained in power for approximately 500 years, the Mossi minority using religion and strong, efficient militaries to maintain control. They successfully repelled attempts by the Mali and Songhai Empires to take control of the area from the 14th to the 16th century and remained in power after the trans-Saharan trade diminished in the 17th century. Not until the 19th century, with the arrival of the French, were the Mossi states dissolved: Yatenga was made a protectorate through peaceful negotiations in 1895, Ougadougou was taken by force in 1896, and Gourma was annexed, along with several other territories, in 1897.

Burkina Faso was split and redrawn several times during the colonial period: Its current borders were established in 1947. In 1960, the country achieved its independence, calling itself Upper Volta, after the territory name given to it by the French.

The country experienced considerable political upheaval in the decades following independence. The country's first president, Maurice Yaméogo, was ousted in a bloodless coup in 1966 by Sangoulé Lamizana, a colonel in Yaméogo's army, which began a trend of military takeovers in the country.

The country was renamed Burkina Faso in 1984 in symbolic rejection of the country's colonial past, but

Burkina Faso remains economically dependent upon FRANCE. Attempts at attracting foreign investment and multiparty elections in 2002 have provided Burkina Faso political stability.

## Burundi

**Map Page** 1114 **Area** 10,759 square mi (27,830 square km) **Population** 6,096,156 **Capital** Bujumbura **Highest Point** 8,760 ft (2,670 m) **Lowest Point** 2,539 ft (772 m) **GDP per capita** \$600 **Primary Natural Resources** coffee, tea, cotton, minerals.

**BURUNDI IS A** landlocked country in eastern Africa. It has borders with the Democratic Republic of the CONGO, RWANDA, and TANZANIA. Burundi is slightly smaller than the state of MARYLAND, and the economy is mostly agricultural. The 1990s represented a tragic time for Burundians. Ethnic genocide in Burundi and neighboring Rwanda contributed to a loss of over 1 million people and displacement of thousands because of an intractable war between the Tutsis and Hutus. Some scholars have speculated that tensions between the Tutsis and Hutus began during the colonial era, especially when the Tutsis were granted power and privilege positions over other ethnic groups. Further escalating the tensions was an institutionalized colonial racial policy that denigrated the Hutus and Twas. Colonialism was essentially a system of political, economic, and cultural domination forcibly imposed by a foreign minority on an indigenous majority.

The country consists of three major ethnic groups: Hutus (85 percent), Tutsis (14 percent), and Twas (1 percent). While Hutus represent the largest ethnic group, Tutsis represent an aristocratic class with lots of economic and political influence in the country. In fact, for many years, Hutus served as servants of local Tutsi aristocrats. Until 1966, the leader of the Tutsi aristocratic

class was the *mwami*, or king. The process of colonialism began when the Burundi kingdom was incorporated into German East Africa in the 1800s. The Germans, and later Belgians, took over the kingdom and established a policy that cemented Burundi's traditional rigid social hierarchy among the Tutsis, Hutus, and Twas.

In the 1950s, Prince Louis Rwagazore, a Tutsi, formed a movement known as UPRONA, with the sole purpose of improving the Tutsi-Hutu relationship. Unfortunately, Rwagazore's untimely assassination ended any peace gesture between Tutsis and Hutus. Despite the setback, UPRONA led the country to independence in 1962. King Mwambutsa IV became the first head of state after independence. Under Mwambutsa's administration, efforts to maintain harmony between Tutsis and Hutus failed in 1965.

First, Hutus soldiers staged a military coup and succeeded in forcing Mwambutsa to go into exile. Second, Tutsi soldiers mounted a counterattack and ended the power grabbed by the Hutus. In the aftermath of the successful counterattack, revenge killings engulfed the country and continued for many years.

In 1993, Burundi's Hutu president was assassinated after only four months in office, thus leading to widespread ethnic violence all over again. An estimated 200,000 Hutus were killed in this round of ethnic strife. The killings and reprisals have created an atmosphere of political instability and uprooted Hutus, many of whom have become refugees in neighboring countries.

Burundi's future looks bleak because of continued ethnic violence and political instability. Despite its rich mineral resource base and generous foreign aid, Burundi is regarded as a very poor country. Additionally, rapid population growth and inadequate agricultural land are hampering efforts to formulate development strategies. In 2002, the Burundi government, dominated by Tutsis, signed a cease-fire agreement with three Hutu groups to end the violence. However, implementation of the agreement is proving to be very difficult, hence delaying any hope for a peaceful end to the conflict.

SAMUEL THOMPSON  
WESTERN ILLINOIS UNIVERSITY

## California

THE MOST POPULOUS state in the UNITED STATES, California also has the richest and most urbanized citizenry. It is the third largest state, famous for its climate, unique industries, agriculture, geographic variety, and lifestyles. California covers 158,706 square mi (411,049 square km), is 252 mi (406 km) at its widest point, and is 824 mi (1,326 km) in length. Its western border is the PACIFIC OCEAN, and the state has 1,931 km (1,200 mi) of shoreline. On the east, most of California borders NEVADA, and in the southeast, the Colorado River separates the state from ARIZONA. OREGON shares the northern boundary, and to the south, California's border is international; the Mexican state of Baja California lies across it. The state capital is at Sacramento, an inland city on the Sacramento River, near the spot where gold was discovered in 1848. Nicknamed "The Golden State," the official motto is "Eureka!" meaning "I found it!"

### GEOGRAPHIC DIVERSITY

An indication of California's geographic diversity is that the highest and lowest points in the contiguous 48 states lie within 85 mi (137 km) of each other in California: Mount Whitney, at 14,505 ft (4,421 m) in height, and Death Valley, at 282 ft (86 m) below sea level. Death Valley, a national park, also is the site of

the highest temperature ever recorded in the United States: 134 degrees F (56.7 degrees C) in 1913.

Almost 28 million acres, or 27.7 percent of the land in California, are devoted to farming. Much of this is in the Central Valley, which extends 450 mi (724 km) along the state's interior, between the coastal and Sierra Nevada mountain ranges. Many large rivers, including the Sacramento, Merced, American, Feather, Tuolumne, and San Joaquin, water the valley, which is called the Sacramento Valley in the north and the San Joaquin Valley in the south. The DELTAS of the Sacramento and San Joaquin rivers divide the two valleys. Grapes are the principal cash crop, bringing in over \$2.5 billion per year; California produces 91 percent of the world's grapes. Lettuce, almonds, strawberries, flowers, tomatoes, and hay follow in order of sales dollars.

The Sierra Nevada are among the highest mountains in the United States and extend in a swath 40 to 80 mi (64 to 129 km) wide, and 430 mi (692 km) long. The range begins south of the active VOLCANO Lassen Peak in the north, slopes upward east of the Central Valley, and continues south to the Tehachapi Mountains. The mountain range's eastern edge is sheer and marked by sudden drops in altitude. Carved by glaciers and continually uplifted by tectonic activity, the Sierra Nevada contains 13 peaks that stand over 14,000 ft (4,267 m) tall. The range is the site of three national

*California's Golden Gate Bridge and San Francisco are one of the gateways on the West Coast of the United States.*

parks: Yosemite, King's Canyon, and Sequoia, as well as Lake Tahoe, a freshwater lake astride the California-Nevada border, 6,229 ft (1,899 m) high, and 1,645 ft (501 m) deep.

North of the Sierra Nevada is an active volcanic area that includes Mount Lassen, Mount Shasta, Medicine Lake Volcano, the Lava Beds National Monument, and the southern edge of the Cascade Range. Directly east of the Sierra Nevada lies the western edge of the Great Basin, a sparse, arid area that extends across much of Nevada and UTAH. It is also called the Trans-Sierra Desert. Both areas are sparsely populated.

California's coastline includes the state's four largest cities: Los Angeles, San Diego, San Jose, and San Francisco, listed in order of population. Three of the four are port communities, which combined, see over \$350 billion in import and export trade per year. Urban areas can extend up to 40 mi (64 km) inland. The coastal areas of California are also made of sandy beaches and dune areas, wetlands, and bluffs.

The Pacific Ocean coast in California is lined with mountain ranges, created by either upthrust magma or the more recent interaction of two tectonic plates, the Pacific Plate and the North American Plate. These mountains affect the state's climate by forming a barrier that prevents the ocean's moisture and storms from traveling further inland. In the far north the Klamath Mountains continue into Oregon. The Coast Ranges are a series of mountains north of San Francisco that reach heights of up to 4,000 ft (1,219 m): the Diablo, Sierra Madre, San Rafael, Gabilan, Santa Cruz, and Santa Lucia mountains.

Below San Francisco, the Transverse Ranges include the Santa Monica Range, which extends offshore to the northern Channel Islands. (While the names of cities and mountains are sometimes the same, they are not necessarily in the same area; the city of Santa Monica is far to the south in Los Angeles County.) Some of the other ranges in the Transverse group, which reaches heights of 10,000 ft (3,048 m), are the Santa Barbara, Santa Ynez, Tehachapi, Topatopa, San Gabriel, and San Bernadino mountains, which stretch as far south as Los Angeles County. South of Los Angeles, the Peninsular Ranges, with altitudes as high as the Transverse Range, includes several groups leading inland as far as the Coachella Valley, as well as the Santa Ana Range that extends out to sea, forming the southern Channel Islands. This group of mountains, which includes the San Jacinto, Santa Rosa, Agua Tibia, and Laguna, continues south into Baja California.

A large portion of the state south and east of the Sierra Nevada comprises the Mojave Desert, which covers one-sixth of California's land mass. Death Valley, the Joshua Tree National Park, and the Havasu National Wildlife Refuge are found here, as well as several military installations, testing grounds, and Indian reservations. The Mojave Desert takes up 25 million acres in California and extends into Nevada and Utah as well. It averages 2,000 to 3,000 feet (610 to 914 m) above sea level, although some areas have much higher and lower altitudes.

South of the Mojave and east of the southern Peninsular Range is the Colorado Desert. This area, which is actually an extension of the Sonoran Desert of Arizona and MEXICO, is less than 1,000 ft (305 m) above sea level in most places. Cotton is a major agricultural product of this thinly populated area.

## CLIMATE

With so much geographic variation, generalizations about California's climate are difficult to make. In most cities of California, though, especially along the coast, winters are much milder than in other areas of similar latitude in the United States. In January, southern metropolitan areas average temperatures of 49 to 65 degrees F (9.5 to 18.3 degrees C), while Bishop, a city east of the Sierra Nevada Mountains in the Great Basin, sees a range of 22 to 54 degrees F (-5.5 to 12.2 degrees C).

In Eureka, a coastal city in the north, the temperature is 41 to 55 degrees F (5 to 12.8 degrees C). Normal high temperatures in July range from 96 to 99 degrees F (35.5 to 37.2 degrees C) in some Central Val-

ley and desert cities, to 63 degrees F (17.2 degrees C) in Eureka. July highs in Los Angeles average 84 degrees F (29 degrees C), and in San Francisco, 68 degrees F (20 degrees C).

Extreme temperatures occur in Death Valley and the high Sierras. The summer heat in Death Valley averages over 100 degrees F (37.8 degrees C), and the area usually gets less than 2 in (5 cm) of rain per year. Higher elevations of the Sierra Nevada get between 70 and 80 in (178 and 203 cm) of precipitation per year, most of it as snow, while desert regions might receive no more than 3 or 4 in (7.6 to 10.2 cm). Along the coast, more rain falls in the north than the south; San Diego, near the border with Mexico, receives less than 11 in (28 cm) per year, while San Francisco gets over 22 in (56 cm).

California was home to Native Americans for at least 15,000 years, and possibly much longer. They formed diverse groups; by the time Europeans encountered the natives of California, there were probably 300,000 people living in the area, speaking over 100 distinct languages. An estimated 500 groups or tri-belets, each with their own customs, beliefs, diets, values, and survival techniques, dotted the landscape. The artistic and complex society of the Chumash on the central coast, who built plank canoes to reach coastal islands, was very different from the small family groups of Paiutes who lived east of the Sierra Nevada Mountains, where resources were scarce. Tribal lifestyles in California were shaped by the land and weather.

Spanish explorer Juan Rodríguez Cabrillo was the first European to sail up the coast of California in 1542. He entered San Diego's harbor, passed San Francisco Bay twice without notice, and died on one of the Channel Islands. Spain claimed the land but saw it only as a port for the Manila galleons that sailed annually between Asia and Mexico. Over two centuries passed before Spain made an attempt to colonize the land they called Alta California. Fray Junípero Serra and soldier Don Gaspar de Portolá led a team of priests and military men north, founding 21 missions, four presidios (forts), and several pueblos (towns) in California through the 1790s.

Along the coast, the Spanish settlements changed and sometimes destroyed native cultures when they attempted to convert, confine, and employ them. Tribes not directly tied to the missions were forced to move or adapt their lifestyles to an environment that changed with the Spanish introduction of new plants, trees, herd animals, and pigs.

*San Francisco's Chinatown reflects the myriad of people and cultures that make up California's population geography.*

Under the Spanish, California's economy came to depend on cattle ranching and the sales of cowhide and tallow. In many inland areas, though, the native groups continued to live as they had for centuries. When Mexico declared independence in 1821, the new government allowed the missions to decline and awarded huge land grants to Mexican citizens.

A small insurrection in 1846 called the Bear Flag Revolt, led by John C. Frémont and other Americans, claimed California for the United States but was abandoned with the outbreak of the Mexican American War. A year later the Treaty of Guadalupe Hidalgo ceded California to the United States as part of the war's settlement. At practically the same time, gold was discovered near Sacramento, on land owned by Swiss immigrant John Sutter. Thousands of gold seekers (called 49ers the first year) flooded California. The state was transformed by the sudden influx of young, mostly white males. San Francisco Bay became a graveyard of abandoned ships; crews as well as passengers flocked to the gold "diggings" along the American, Feather, and Sacramento River and their branches. San Francisco itself boomed from a hamlet of 400 in 1847 to a city of 15,000 by the fall of 1849. In the search for gold, rivers were dammed and diverted, and choked with debris. Channels and pits were gouged out of the landscape, and hillsides were washed away by hydraulic mining. Arsenic-laden piles of tailings—the refuse of processed ore—poisoned land and water.

California became the 31st state in September 1850, and the Mexican citizens who stayed lost most of their lands. A free state, it sided with the North dur-

ing the Civil War but was far from the battlefields. The state continued to grow even after mining lost its appeal, but men outnumbered women for many years, Native populations dwindled, and nonwhites were usually denied citizenship and rights. Chinese immigrants, 25,000 of them almost all male, arrived by 1852, and thousands more were brought to the state in the 1860s to build railroads.

The railroads made millionaires of some and opened the state to more migration from the east. Boosterism (promoting California) and progressivism flourished near the turn of the 20th century. The new film industry centered itself in Hollywood and became a defining symbol of the state. After the 1906 earthquake and fire in San Francisco, the temblor was also associated with the state. California became a leading producer of wheat, fruits, nuts, and vegetables, and water availability became a problem, addressed by projects such as the damming of Hetch Hetchy Valley, and the Los Angeles Aqueduct, which devastated the Owens Valley to bring water to Los Angeles.

Prejudice against the Chinese at the state and national levels led to a halt in immigration from China, and by 1910, 40,000 Japanese laborers entered California to work. The state, always prey to a “boom and bust” cycle of growth, barred and discriminated against immigrants in economic downturns. During the Depression, interstate migrants from the Dust Bowl were turned away at the border.

World War II brought the aircraft industry to California, along with increased shipbuilding and weapons production. The sunny climate and available land for training and testing were factors that attracted wartime industry, and California remained a major center for military and defense work into the 21st century. This brought many minorities to the state to fill jobs. Much of California’s large Japanese population, however, was forced into internment camps during the war.

After the war, sprawling suburbs grew around cities to accommodate workers of the new technical and aerospace industries. California’s liberal governor Earl Warren, a Republican, like most of his predecessors since the Civil War, left office to lead the U.S. Supreme Court in 1953. California emerged as center of protest and innovation during the 1960s, and San Francisco became a haven for the counterculture movement.

The Watts riots in Los Angeles focused attention on civil rights issues, the free speech movement at the University of California at Berkeley turned to active protests and sit-ins, the Black Panthers and Chicano

student organizations were formed, and the American Indian Movement (AIM) occupied Alcatraz Island, a former prison in San Francisco Bay.

The technical industries of California expanded in the 1970s and 1980s to include new computer and microchip businesses, and Silicon Valley in the north became a major center of information technology. Environmental concerns over toxic dumping and emissions, smog, and pesticide use in agricultural areas rose during the same period. Immigration, both international and interstate, continued to inflate the population. In the 1970s, San Francisco became a center for the gay community, and the sexual orientation of the city’s residents has been at least 15 percent gay since. In 2004, the city issued 4,037 same-sex marriage licenses before ordered to stop by the state supreme court.

In the 1990s, Los Angeles suffered further riots, and the state experienced natural disasters, including large earthquakes, fires, droughts, flooding, and mudslides, combined with economic ups and downs. California shares the same concerns and challenges as the rest of the nation as it enters the 21st century, but with a larger share of population, land, and business than most other states, California has become both a leader and a test case for new ventures, ideas, and lifestyles.

## POPULATION

As of July 2003, the state was home to 35,934,000 people: 28 percent, or 10 million people, live in Los Angeles County; six other counties have over 1 million residents. For historical context, after the initial gold rush, California in 1850 had 92,000 people (excluding Native Americans), by 1870, 0.5 million, and in 1900, 1.5 million people. In 1941 the state was home to just over 7 million people; by 1957 that figure had doubled. The population in 1970 was 20 million, in 1980 almost 24 million, and in 1990, 30 million. California’s population is slightly younger than the national average, with only 10.6 percent over age 65 (nationally, 12.4 percent are over 65), and 27.3 percent under age 18 (compared to 25.7 percent nationally).

About half of the new residents in California in 2003 were immigrants; 49 percent of that number came from Latin America and the Caribbean, and 40 percent came from Asia. California has had the highest population of immigrants for several years; over 27 percent of immigrants to the United States live there. The 2000 U.S. census reports that of almost 35 million people in California, 16 million claimed to be white, 11 million Hispanic, 2.2 million Black, and 3.7 million Asian in ethnicity. Over 900,000 said they were mul-

tiracial, 104,000 were Hawaiian or Pacific Islanders, and 179,000 claimed American Indian or Native Alaskan heritage.

## ECONOMY

California boasts the fifth-largest economy in the world and the largest in the United States. Its gross state product in 2003 was \$1.4 trillion. Although a 2004 study put California second (behind Massachusetts) in its ability to attract and develop high-tech business, all projections are impacted by fiscal and budget problems that led to the 2003 recall election of the state's governor, Gray Davis. Davis was replaced by Republican Arnold Schwarzenegger, who proposed massive cuts and changes in the state's spending to bring the deficit under control.

Tourism, the entertainment business, aerospace, electronics, and high-tech industries are all areas in which California dominates other states. California's agricultural production, including both farm and cattle products, exceeded \$27.6 billion in 2001. There were 88,000 farms in the state, covering 27.7 million acres. California produced over 90 percent of the world's grape products, and in 2003, almost 500 million gallons of California wine were shipped worldwide. In 2001, about 19 percent of Californians worked in trade, transportation and utilities, 15 percent provided professional services, 15 percent worked for the government, 11 percent for manufacturers, and 10 percent in education and health fields.

Over the years, the unemployment rate has remained higher than the national average; in 2003 California saw 6.7 percent unemployment, compared to the nation's 6.0 percent. Average personal income in California has historically been higher than that of the rest of the United States, but the percentage has steadily declined. In 1955, Californians earned 24.5 percent more per capita, but in 2002 a Californian earned only 6.7 percent more than people in other states, on average.

## Cambodia

**Map Page** 1124 **Area** 69,884 square mi (181,040 square km) **Population** 13,124,764 (2003) **Capital** Phnom Penh **Highest Point** 5,938 ft (1,810 m) **Lowest Point** 0 m **GDP per capita** \$278 **Primary Natural Resources** timber, gemstones, hydropower potential.

BORDERED BY VIETNAM, LAOS, and THAILAND, Cambodia, with a near circular shape, is a perfect example of a compact country. The country can be divided into several physical units: Elephant and Cardamom mountains to the southeast, parts of Annamite Cordillera to the northwest, upper part of the Mekong delta to the southeast, Tonle Sap Lake and its basin to the center and the west and the Mekong River basin between the Cordillera and Tonle Sap. As the Mekong floodwaters rise, there is a reverse (westward) flow into Tonle Sap, which increases the lake depth by over six times. Tonle Sap thus takes up the excess Mekong waters during the monsoon. Thereafter, the lake water resumes its normal eastward flow to Mekong.

Three distinct cultural-historical core regions (Funan, Angkor, and Phnom Penh) can be identified in Cambodia, stretching over a period of 2,000 years. Funan's (1st to 7th centuries) capital was on the Mekong Delta at Vyadhapura (Banam). The Funan society and political system were highly influenced by Indian conquests. The Khmers established a powerful core area based in the Angkor area (802–1432). The Khmer kingship gave rise to one of the most powerful and long-lasting theocratic states in the world and determined not only the dynastic lineage but also the political, social, economic, and agricultural features of the land. Productivity of the land and the belief of the people in a god-king were at the roots of Angkor's power base. The demise of the Angkor core may be at-

tributed to loss of agricultural surplus, depopulation due to malaria, and army weakness.

After the fall and disappearance of Angkor, Phnom Penh emerged as a core region ruled by different rulers. French occupation of Cambodia lasted 90 years (1863–1953). The country got its independence in 1953 and had a stable government between 1953 and 1969 under the leadership of Prince Sihanouk, who abdicated his throne in 1955 and organized state elections for the first time in Cambodian history. After the coup d'état staged in 1970 by his prime minister, Lon Nol, Cambodia came under military rule.

### KHMER ROUGE

The Khmer Rouge (Communist Party) led by Maoist premier Pol Pot displaced Lon Nol in 1975. Khmer Rouge considered cities to be parasites living on agricultural surplus. Thousands of city dwellers were driven out to villages in order to increase rice production. Phnom Penh's population was reduced to 200,000 from 2,000,000 in 1976. Formal schooling was abandoned. Religion was virtually abolished, while pagodas were converted into storage and military places. In the process, 1 million people died between 1975 and 1978.

In 1991, a Cambodian peace agreement was signed. The new government established rights to freedom of political beliefs, assembly, and publication and a market-based economy. However, Cambodia remains troubled by unrelenting political volatility and insurgence. Cambodia is one of the poorest countries of the world. Population growth has been uneven because of political and social events. The infant mortality rate (76 per 1,000) is high, and a large proportion of the population (39 percent) is under 15. Presently, population growth is slow (1.8 percent annually) due to the AIDS epidemic; 170,000 persons lived with HIV/AIDS in 2001. Cambodia is essentially a rice-growing agricultural country with 80 percent of its labor force engaged in agriculture. Only 20 percent of its GDP is derived from industries that include garment making, rice milling, wood products, and rubber. Tourism is the country's fastest-growing industry.

## Cameroon

**Map Page** 1115 **Area** 183,569 square mi (475,440 square km) **Population** 15,456,000 **Capital** Yaoundé **Highest Point** 13,435 ft (4,095 m) **Lowest Point** 0 m **GDP per capita** \$2,100 **Primary Natural Resources** petroleum, bauxite, iron ore, timber

**CAMEROON IS A** triangle-shaped nation slightly larger than CALIFORNIA. It is wedged between NIGERIA and EQUATORIAL GUINEA on Africa's west-central Atlantic coast at the Bight of Biafra.

The country has varied terrain with western mountains, northern grasslands, and tropical lowlands in the south. Forests line the Atlantic coast. Grassy savannas stretch northeast to marshes on Lake CHAD. To the east is the CENTRAL AFRICAN REPUBLIC. To the south are GABON and CONGO.

Tourism is limited, but recreational areas include beaches near Kribi and abundant wildlife within the national parks, particularly herds of elephants protected in Waza National Park. Archaeologists' findings of stone tools and rock carvings indicate that prehistoric peoples preceded the Bantu speakers who first came to the northern highlands about 2,000 years ago. A state called Kanem existed during the 8th century and included parts of present-day Cameroon. Today, the population includes pygmy tribes and 200 different ethnic groups from 24 different language groups and 80 distinct dialects. The largest tribes are Bamileke (30 percent) and Fulani (7 percent). The predominant religions are animist (51 percent), Christianity (33 percent), and Islam (16 percent).

The country's name comes from the Portuguese word for shrimp after European explorers in the 1400s who found small crayfish that looked like shrimp in the Wouri River. Slave trading flourished from the 15th century well into the mid-1800s; thousands died fight-

ing slave raiders or suffering from cruel conditions en route to the Western and Arabic worlds, where they were forced into unpaid labor and considered owned property.

In 1858, British missionaries established the first permanent European settlement in Cameroon, the town of Victoria at the base of Mount Cameroon. The UNITED KINGDOM, FRANCE, and GERMANY struggled for control during the 1800s, then in 1884 two tribal chiefs signed a treaty that made Cameroon a German protectorate until 1916. Under terms of the World War I Armistice, France and Britain divided the territory and later received League of Nations mandates, then United Nations trusteeships. Both pledged in 1946 to grant self-governance. French Cameroon became independent on January 1, 1960. In February 1961, British Cameroons voters in the north chose to merge with Nigeria, while voters in the south chose Cameroon.

Cameroon is divided into 10 provinces, each headed by a governor appointed by the president, who as head of state holds the most governmental power and is elected to a seven-year term. In the National Assembly, 180 legislators are elected to five-year terms. Cameroon's chief political party is the Cameroon People's Democratic Movement and was the only party allowed until 1991.

Coffee, cocoa, cotton, rubber, bananas, livestock, and timber are Cameroon's major products, but petroleum is the primary export.

## Canada

**Map Page** 1135 **Area** 3,850,000 square mi (9,984,670 square km) **Capital** Ottawa **Population** 32,207,113 **Highest Point** 19,550 ft (5,959 m) **Lowest Point** 0 m **GDP per capita** \$29,800 **Primary Natural Resources** iron ore, nickel, zinc, copper, gold.

CANADA ENCOMPASSES the second-largest land area of any country after RUSSIA. Like its southern neighbor, the UNITED STATES, Canada's terrain varies quite dramatically and is divided into multiple geographical areas.

The CANADIAN SHIELD, which is the largest geographical area, encompasses half the country and centers on Hudson Bay. This horseshoe-shaped region reaches northward from the U.S. border and covers the area from the Gulf of St. Lawrence in the east, south to the Great Lakes, and west to the Great Slave Lake in the province of Vancouver. The Canadian Shield was carved during the last Ice Age, when glaciers moved across the land, scraping away the soil, damming rivers, and creating lakes. Its rivers are the heart of Canada's hydropower industry.

The southeastern region of Canada consists of lowlands, bordered by the Great Lakes: Lake MICHIGAN, Lake SUPERIOR, Lake ERIE, and Lake ONTARIO. It is segmented by the ST. LAWRENCE RIVER, which is an important shipping lane. The St. Lawrence River flows downward toward the ocean from the Great Lakes, which are above sea level. A series of locks help to move the ships upstream. Montreal sits at what is the head of navigation on the river, the point at which the ships can go no further due to rapids or waterfalls.

### ERODED MOUNTAINS

Further north and east, the APPALACHIAN MOUNTAINS extend north from the United States. This mountain range is a chain of older, well-eroded mountains that were created by glacial activity. The eastern region of Canada is heavily forested. The tree line or boreal forest consists of coniferous (evergreen) trees and extends across the Ungava Peninsula to the lower Mackenzie Valley and ALASKA. North of this area, the poor soil quality supports little vegetation beyond hardy, shallow-rooted tundra plants such as lichens and mosses. Because of the cold temperatures, the soil below the top layer of soil is permanently frozen and does not thaw even in the summer months.

South-central Canada consists of rich, flat farmland and lakes. To the west, the plains give way to PLATEAUS and river channels that were carved by glacial activity during the last Ice Age. Western Canada is home to the Canadian Cordillera, a system of rugged mountains that include the St. Elias, Mackenzie, and Rocky Mountain ranges.

Canada's highest mountain, Mount Logan (19,550 ft or 5,959 m), is a part of the St. Elias Mountain Range. The western coast consists of dense forests and moun-

*Vancouver, British Columbia, is Canada's major metropolis on the Pacific Ocean coast.*

tains that are the source for three of Canada's major rivers: the Columbia, the Yukon, and the Fraser. These rivers serve as important parts of Canada's hydropower industry. The western port of Vancouver, Canada's third-largest city, serves as Canada's main port for the exportation of wheat, coal, and lumber to Asia.

Northern Canada consists largely of year-round permafrost and frozen tundra. Due to the extreme temperatures in the winter, less than 1 percent of Canada's population lives in the northern territories and many who live in the north are Inuit Amerindian.

## CLIMATE

Canada has four distinctive seasons. The timing of each of these seasons changes, according to latitude. The Canadian CLIMATE is subarctic throughout most of the country. On average, temperatures are cool in the summer and sub-freezing during the winter, with the average temperature hanging below 0 degrees F and C. In northern Canada, winter begins in August and runs through March, and daylight is extremely limited. In the Arctic regions of northern Canada, there is no sunlight for six months of the year.

In the southern part of the country, summers and winters are much more temperate. Temperatures can reach the lower 80s F (upper 20s C) during the summers. The mildest winters occur in the southeast and along the western coast.

The east and west coasts tend to be wet year-round, and the western coast experiences heavy seasonal rains during the winter months. The movement of air across

the plains to the Canadian ROCKY MOUNTAINS causes air flow patterns that can produce cyclic storms to the east of the mountains during the winter. The Canadian Central Plains themselves are generally quite arid year-round, although thunderstorms mitigate some of the dryness during the summer.

## ENVIRONMENT

Canada's mining industries, as well as coal-burning and vehicle emissions, have caused significant problems with air pollution, water contamination in the oceans, and acid rain. The country is also prone to several environmental hazards. The west coast of Canada (mostly British Columbia), is a part of the Pacific Rim, or RING OF FIRE.

The Ring of Fire is marked by its unusual number of volcanoes. The west coast of the Canadian province of British Columbia and the southern part of the Yukon include many volcanoes. There have been no recent eruptions, but many of these volcanoes remain active today. Due to its location along the Ring of Fire, Canada's western coast is also vulnerable to tsunami activity, which may result from seismic or volcanic activity elsewhere in the Pacific.

Canada also records approximately 9,000 forest fires throughout the country every summer. Most of these fires are caused by lightning strikes.

## GOVERNMENT

The seat of the Canadian national government is located in Ottawa, a city that is situated in the southern part of the province of Ontario. Canada is sub-divided into 10 administrative provinces (the capitals are in parentheses): Newfoundland (St. John's), Nova Scotia (Halifax), New Brunswick (Fredericton), Prince Edward Island (Charlottetown), Quebec (Montreal), Alberta (Edmonton), Saskatchewan (Regina), British Columbia (Victoria), Ontario (Toronto), and Manitoba (Winnipeg). Provincial governments mirror the national government. Their responsibilities include civil law, local taxation, land management, local trade, health, welfare, and education.

Newfoundland, Prince Edward Island, Nova Scotia and New Brunswick, which are all peninsulas, make up what is known as the Atlantic Provinces. Halifax is the largest city, and serves as an important port, as it remains free of ice year-round, making it easily accessible to ships in the winter, when many other ports are iced in. The bulk of the population of the Atlantic Provinces lives along the coast, and many make their livelihoods from the sea.

Since the 1960s, there has been a separatist movement within Quebec, where the majority of the population is of French ancestry rather than the Anglican ancestry shared by most of the population. Thus far, any attempts to secede from Canada have proven unsuccessful. In addition to its 10 administrative provinces, Canada has three dependent territories. The Yukon and Northwest territories, which are very sparsely populated, are administered by the federal government. Nunavut became the newest territory of Canada on April 1, 1999, when the Northwest Territories was divided into two parts. The part to the east of the dividing line became Nunavut, whereas the part to the west became a new territory that retained the name Northwest Territories.

## ECONOMY

The Canadian economy is heavily dependent on trade, particularly with the United States. The NORTH AMERICAN FREE TRADE AGREEMENT (NAFTA) has permitted relatively unrestricted trade between Canada, the United States, and MEXICO. Dominant industries include mining, forestry, agriculture, and fishing. Most of the agriculture occurs in the southern part of the country, because of short growing seasons further north. Wheat is the most predominant cash crop, although corn, soybeans, and tobacco are also significant crops. In the western prairies, most agriculture consists of raising livestock, particularly sheep, cattle, and pigs.

Most of the fishing industry is centered along the east coast, around Labrador. However, there is some salmon fishing in the west. Also in the west, British Columbia is home to Canada's forest industry, where there is significant production of wood pulp and paper. The western part of the country is also home to Canada's primary mineral resources: oil, gas, and coal. Further east and north, the mining industry is focused on zinc, iron, nickel, copper, lead, uranium, and potash.

## HISTORY

Like most of North America, Canada's first settlers are generally believed to have arrived across the Bering Strait from SIBERIA via a now-defunct land bridge approximately 10,000 to 30,000 years ago and disseminated throughout the continent. A second wave of settlers, who are the ancestors of the Inuit people, arrived around 4000 B.C.E.

The Vikings were the first Europeans to reach Canada, most notably Leif Eriksson and Thorfinn Karlsefni around 1000 C.E. The Vikings did not stay however, and the next Europeans did not arrive until

*Banff, Alberta, is one of Canada's several cities located in the country's isolated and vast northward interior.*

Italian navigator John Cabot's expedition landed at Newfoundland in 1497. By the 16th century, French and English explorers, including Jacques Cartier and Samuel de Champlain, arrived and began to explore Canada's interior. Cartier gave Canada its name, following a misunderstanding regarding the Iroquois word for "village." When Cartier asked the Iroquois the name of his location, they answered "Kanata." Cartier and the other explorers who were with him began to refer to that location (now Quebec City) as "Kanata," anglicizing it to "Canada."

Canada remained a subject of exploration for those who hoped to find a northwest passage between the Atlantic and Pacific Oceans that might facilitate trade between Europe and Asia. Henry Hudson, who led the ship *Discovery* in 1610, was one of the earliest explorers who sought such a passage. Although Hudson was unsuccessful, his quest did lead to a charter to be commissioned by King Charles II of England in 1670. This charter granted Prince Rupert and 17 other men sole trading rights on all lands whose rivers drained into Hudson Bay, an area that encompassed nearly 40 percent of Canada. Rupert and the other men became known as the Governor and Company of Adventurers Trading into Hudson Bay. They are considered to be the first governors of the English colony. This early federal state included portions of what are now the Canadian provinces of Quebec, Nova Scotia, and New Brunswick.

The settlement of Canada occurred first in the east, along the Atlantic coast and Hudson Bay area. The French quickly colonized the region around the St.

Lawrence River and the Great Lakes between Quebec and Montreal. The French settlers began a thriving fur trade, although conflicts over settlement rights grew between the French and English settlers. These conflicts culminated in the capture of Quebec and Montreal by British General James Wolfe. The tension was resolved, at least temporarily, by a treaty that was signed in Paris in 1763 that turned the lands over to the British.

Canada became even more of a British stronghold during the years of the American Revolutionary War, when British loyalists fled to Canada. Two distinct colonies, Upper and Lower Canada, were created by a constitutional act in 1791. Dissension led to an unsuccessful revolt in 1837, although political reform resulted, including the fusion of the two colonies.

In 1845, a second famous attempt to find a northwestern passage took place. Englishman Sir John Franklin took 128 men and two ships, the *Terror* and the *Erebus*. Franklin's mission was commissioned by Sir John Barrow, England's Secretary of the Admiralty. Franklin and crew were directed to sail through Lancaster Sound and Barrow Strait and to get as close as possible to the Bering Strait by traveling southwest. Franklin and company were last seen on July 26, 1845. By 1848, when no word had been received from the expedition, a small rescue mission of three teams was dispatched to search for them. None of the three teams was successful and neither Franklin nor any members of his crew was ever seen or heard from again.

The gold rushes of the 19th century served as important catalysts in the interest, acquisition, and settlement of what is now western Canada. Canada gained territory in the west in 1849, with the creation of the colony of Victoria, which is located on the island of Vancouver, off the coast of British Columbia. Canada expanded again in 1858 as the result of the gold rush, and British Columbia was added to the growing British colony. During this time period, Canada experienced an increasing population, including an influx of immigrants from other European countries, including Russia.

Until the cessation of slavery, Canada also served as a refuge for African-Americans who had escaped from slavery in the southern United States. Canada officially became the Dominion of Canada in 1867, under the British North America Act. The provinces of Quebec, Ontario, Nova Scotia, and New Brunswick were all added at this time.

A second gold rush occurred in the late 19th century, known as the Klondike Rush. Prospectors who

had been working in the region of modern-day San Francisco, heard rumors of gold being discovered in the Yukon Territory. Thousands of would-be miners came pouring into the sleepy lumber mill town of Dawson City, which had been founded near the junctions of the Yukon and Klondike rivers by Joseph Ladue in 1896 and named after George M. Dawson, who had led a geographic survey of the Northwest Territories in 1887. The area remained busy with prospecting activities for approximately three years, after which the prospectors moved on when gold was discovered in Nome, ALASKA.

The later half of the 19th and early 20th century proved to be a time of accelerated geographic expansion for Canada. Although some of the expansions and geographic changes involved the redrawing of boundaries of existing western and eastern settlements, much of the expansion included additional territories in the northwest as well as the acquisition of lands that are now a part of central Canada. The government purchased the Northwest Territories from the Hudson Bay Companies in 1870. In the next 35 years, Manitoba (1870), Prince Edward Island (1873), the Yukon Territory (1898), and Saskatchewan and Alberta (both 1905) all joined the Dominion.

As in the United States, the geographic expansion of the European settlers proved to be problematic for the native peoples. Settlers encroached on native lands and destroyed the bison, which were an important food source and resource. Tensions flared and culminated in an armed uprising in the later half of the 19th century by the Métis, who were of French and native ancestry. The uprising was unsuccessful and Louis Riel, who led the uprising, was executed in 1885.

Britain granted increase autonomy to the Dominion in 1931, in recognition of its support for the Allies during World War I. Twenty-one years later, in 1982, Canada gained full control of its constitution. The Canadian Constitution replaced the British North America Act and guarantees such rights as freedom of religion, speech, association, and the press. Canada has remained geographically stable since this time.

## Canadian Shield

THE CANADIAN or Laurentian Shield, the largest natural region of North America at 1.1 million square mi (3 million square km), is located north of the St. Lawrence Lowland and east of the Interior Plains. It is composed of igneous and metamorphic rock of Precambrian origin, some of the oldest rock on Earth. More than 80 percent of the surface is exposed gneissic granite, basement rock at the surface, the product of intense glacial action and erosion over the past half billion years. Glacier ice scoured the rock and sculpted river valleys, dragged and laid down boulders called erratics, and severely disrupted the surface drainage pattern. The shield is largely devoid of soil and dotted by hundreds of thousands of swamps, lakes, rivers, and streams. The shield is stable continental crust gently rolling in character (under 2,000 ft or 600 m) with occasional prominent uplifts of crustal blocks. One sees the sharpest local relief along the southern edge, especially the Laurentide Escarpment in Quebec. The shield exhibits a bowl shape as it slopes gently northward to Hudson Bay. Glacial debris has been deposited in river valleys and lowlands to considerable depths, such as around James Bay and Hudson Bay, giving the landscapes a notable flatness.

Long, cold winters and short, cool summers characterize the region. Though primarily rock, water, and ice, the shield also hosts a vast boreal or softwood forest of spruce, fir, pines, and tamaracks, tall and dense in the south to short and sparse in the north. Soils are poorly drained, acidic, and thin, and therefore of limited value to agriculture. These soils are mainly spodosols, associated with evergreen forest, while the northern TUNDRA soils are heavily moisture laden and frozen for much of the year. Fertile soils are limited to a few river valleys where deposition has been significant.

The shield effectively divided eastern and western CANADA and posed a major barrier to westward migration. The Hudson's Bay Company created a trade monopoly across the region and laid the basis for a

network of extractive industries. Settlements today are mostly small, widely dispersed, have narrowly based economies based on extractive industries such as mining, and are controlled largely by the urban-industrial core to the south. Sudbury, Ontario, at 160,500 is the largest metropolitan center in the region, followed by Thunder Bay, Ontario, at 125,000.

Inuit and native populations are well represented on the shield, although in scattered locations, and the population in general faces limited economic opportunities, unemployment, and related social problems. The shield has figured prominently in the development of Canadian character and culture, as evidenced in everything from art and music to the stories of Jack London.

Metallic ores are concentrated in an arc between the North ATLANTIC OCEAN, ST. LAWRENCE RIVER, and the Arctic as, for example, nickel at Sudbury, copper-lead-zinc at Flin Flon, and iron ore on the Quebec-Labrador border and in western Ontario. Access is a critical issue, especially for extractive industries like mining and lumbering that depend heavily on overland transport. Construction costs are high over vast distances of rocky, ill-drained surfaces where population densities are low. Railroad lines extend from the Prairie Provinces to Churchill on Hudson Bay as well as to mining developments on the Great Slave Lake, Northwest Territories, and to James Bay in Quebec. Helicopter and small plane services are integral to the region. All in all, transportation networks are not well developed, and communities face ongoing problems of isolation, high costs, and uneven integration into the Canadian economy.

The shield holds great hydroelectric potential, especially along its southern edge where local relief is most abrupt. Power stations at Churchill Falls, Labrador, and James Bay, Quebec, are the shield's two largest hydroelectric developments. Power is abundant, sold to markets in the northeastern UNITED STATES, and important as cheap energy for aluminum manufacturing, lumber processing, and other shield industries. Intimate functional relationships have grown up between the resource areas of the shield and the processing industries of the St. Lawrence Valley. Tourism is a fast-developing industry, especially on the southern margins, and is accompanied by growing public concern over preservation of the fragile shield environment.

## Canary Islands

THE CANARY ISLANDS lie just 93 mi (150 km) off the northwest coast of Africa in the ATLANTIC OCEAN but have been politically and culturally attached to SPAIN, 830 mi (1,350 km) to the northeast, since the 14th century. Today the seven islands, an autonomous region of Spain, are among the most popular holiday destinations for tourists from northern Europe.

The islands' proximity to Africa is apparent in their climate, an extension of the deserts of the SAHARA. Some areas are semiarid, with abundant cacti and *maspalomas* (large sand dunes), while higher elevations host laurel and pine forests, with subtropical and tropical plants in the valleys in between. The islands are volcanic in origin and reflect this in their steep inclines and rugged cliffs. They vary in age and volcanic activity, from the oldest, Fuerteventura and Lanzarote in the east, to the most recently formed La Palma and El Hierro, furthest west in the chain. La Palma has seven volcanoes that have erupted since the 15th century, most recently Teneguía, in 1971. It also has a large collapsed caldera in the center of the island (Taburiente), with a rim averaging 6,600 ft (2,000 m) in height and an astronomical observatory.

Between these extremes of old and new islands at the eastern and western ends of the chain, lie the largest and most populated of the Canary Islands, Tenerife and Gran Canaria. Most of the beach resorts and nightclubs are on these two islands, but they too have their share of scenic ravines and mountain peaks—Pico del Teide is the highest point not only in the Canary Islands, but in all of Spain. Lastly, the small island of La Gomera, where isolation has best preserved the indigenous culture of the Guanches people, including their distinctive pottery made without a wheel, and the famous whistling language, Silbo, used by shepherds to communicate between sharp valleys and cliffs for centuries.

The Guanches are believed to be immigrants from North Africa, but legends name them as the only sur-

vivors of the lost continent of Atlantis. The ancient Greeks knew of the islands, as the last known land after the Pillars of Hercules (the Straits of Gibraltar). They were known as “the Happy Isles” before cartographers started calling them the Canaries—possibly due to the large hunting dogs (*canis* in Latin), still bred on the islands today (called *verdinós* or *bardinós*). But little was known about the islands until they were visited by a Genoese explorer, Lancelotto Malocello in 1312 (giving his name to Lanzarote). Ancient mariners drew the first meridian at El Hierro, marking the western edge of the world (today this is the west 18th).

Spanish monarchs established control over all of the islands between 1402 and 1504 and resisted repeated attempts by the Dutch and English to take the islands. The islands were coveted as the important last stop before setting off to cross the Atlantic, starting with Columbus himself, who last saw land at La Gomera on September 6, 1492. The islands formed two provinces, Santa Cruz de Tenerife and Las Palmas, until the reorganization of Spain into regions in 1984, which made the Canaries one region, with relative internal autonomy. Less than 10 percent of the gross domestic product is generated by agriculture, mostly bananas, especially on Tenerife, but also figs, grapes, and almonds in areas with a more Mediterranean climate. Rather, it is tourism—over four million visitors a year come to Tenerife alone—that contributes most to the local economy and provides residents with a per capita income higher than that of mainland Spain.

## canyon

A CANYON IS A deep, narrow passage cut through the surface of the Earth with steep cliffs on both sides. Sometimes called a gorge or ravine, canyons are often formed in mountainous, arid, or semiarid regions where riparian EROSION is much greater than erosion from general weathering. They range in size from an arroyo, or ditch, to the GRAND CANYON, with its depth of more than a mile. Canyons can be found all over the world, at the bottom of the ocean, and even on other

planets. The word *canyon* is thought to originate in the Spanish *cañon*, which means “tube” (from the Latin *canna*, a reed). This root is descriptively accurate because canyons are frequently in the shape of a tube, having been carved by the constant flow of water between surrounding walls.

Canyons are formed and deepened by erosion from moving water and may be widened by landslides. A number of canyons were carved out of the Earth by massive glaciers, some more than a mile thick, which took millions of years to cut their way through solid stone. As the surface of the Earth has been shaped by climate over eons, cycles of ice age followed by thaw have occurred, and much land that is desert today was under water at some time, submerged below ancient seas.

These ancient seas deposited sediments, which settled in layers, and nowhere are those layers more evident than in the walls of a canyon. As snows melt and collect in rivers, the force of water slowly carves channels through these layers, exposing the history of the land in a sedimentary cross-section of Earth. These exposed layers offer an excellent living laboratory for scientists to study the geological changes in the Earth's crust. For example, at the Grand Canyon's rim, the Earth is only 250 million years old in places; on the floor of the canyon, the most ancient layers are thought to be up to 1,200 million years old.

As rivers erode deep into the canyon floor, they become entrenched and cannot easily alter their course, thereby deepening themselves further, faster. These rivers become deeper and canyon walls become higher and higher. The Grand Canyon slices through the Earth's crust for 217 mi (347 km) miles from beginning to end. It averages 10 mi (16 km) across—almost 20 mi (32 km) at some spots—and over 1 mi (1.6 km) deep. The Snake River and its Hells Canyon are another example of river entrenchment; while such canyons are massive, they are not the biggest on Earth. That honor goes to the canyons that form on the ocean floor, called submarine canyons.

Submarine canyons, forged by some of the same forces as canyons above sea level, dwarf the Grand Canyon in magnitude. The force of rivers emptying into the ocean, massive underwater landslides, and mudflows combine to carve out submarine canyons. One of the largest of these canyons, the Great Bahamas Canyon or Trench, measures 14,000 ft (4,575 m) from rim to floor; that's twice as deep as the Grand Canyon.

As impressive as these numbers are, the biggest canyons in the solar system are not found on Earth. On

the planet Mars, the Valles Marineris canyon system spans over 2,500 mi (4,000 km) from end to end—about the distance from New York to San Francisco—and has a depth of up to 6.25 mi (10 km). Scientists are interested in canyons on Mars because they may indicate the presence of water at some time in the planet's history, and the presence of water on Mars—confirmed by NASA's 2004 robotic-lander mission to the Red Planet—indicates the possible presence of life.

Canyons are important for many reasons. Their striking beauty and the diverse flora and fauna that flourish there enrich the landscape and the lives of the people who experience them. They can provide information about climate changes in the past and may help predict climate changes in the future. They are also important to archaeologists because of the artwork and fossils found on canyon walls, and the cliff dwellings built in the steep walls of some canyons can teach us about ancient cultures.

## Cape Verde

**Map Page** 1113 **Area** 1,557 square mi (4,033 square km) **Population** 412,137 **Capital** Praia **Highest Point** Mt. Fogo 9,281 ft (2,829 m) **Lowest Point** 0 m **GDP per capita** \$1,400 **Primary Natural Resources** salt, basalt, limestone, kaolin, fish.

CAPE VERDE IS a volcanically produced archipelago, consisting of 10 major islands and five islets in the ATLANTIC OCEAN, 285 mi (460 km) off the coast of SENE-

GAL in Africa. Settled by the Portuguese sometime between 1455 to 1461, the uninhabited and resource-poor Cape Verdes offered an early lesson in what today's marketing gurus refer to as: "location, location, location." The craggy islands, with their hot, dry climate, were of little intrinsic value. Rain came sporadically, but sometimes in torrents, ruining whatever crops might otherwise grow.

Trade winds swept early sail-powered vessels to Cape Verde, and PORTUGAL capitalized, vigorously, on the islands' location. Descending from north to south, the AZORES, Madeiras, and Cape Verde formed strategically positioned stepping-stones to and from the Atlantic for Portugal. Their natural and manufactured resources were collectively leveraged for the Crown, and also offered an African trade axis with its own cultural and economic attributes.

Portugal carefully planned its colonial economies. Goats, which could survive virtually any terrain, were brought to Cape Verde even before settlers. A preservative and dietary supplement for long transoceanic voyages, salt proved to be the only redeemable natural resource. The Portuguese also envisioned Cape Verde as a trade outlet for their naval stores, but proximity to the African coast rendered slave-trading the largest commercial activity, peaking in the first half of the 17th century and ending in the early 19th, when most of the world outlawed it. In order to settle the islands and bolster their profitability, the Portuguese crown initially extended trade privileges to private firms and issued land grants with the hope of seeding plantation-style agriculture. (Farming largely failed. Ironically, some of the best-growing crops, notably beans and squashes, were New World imports.)

Less privileged individuals arrived at Cape Verde, too: Former prisoners brought at government behest for their labor; Iberian Jews fleeing the Inquisition; independent adventurers of truly diverse nationalities; slaves and freed slaves (often liberated during times of extreme drought/famine when even wealthy Cape Verdeans could not provide for them); and their well-mixed progeny.

The early elite profited from government-granted status, but others were forbidden to trade with foreign countries and limited in what they could exchange (no guns to Africa, for example). They frequently flouted colonial dictates and embarked on their own trade, sometimes through smuggling. Generally, they learned to navigate—both commercially and culturally—the African coast with its myriad tribal leaderships. Three major trade classes subsequently emerged: *tangomaus*,

originally black African traders who adapted to Portuguese culture; *lancados*, white Portuguese who ventured from Cape Verde to Africa; and *grumetes*, black or mixed-race servants who worked the boats and hauled cargo.

With the end of slave trading, Cape Verde returned to provisioning. Faster, more efficient steam ships plied the seas, and newly discovered coal and a good harbor at Mindelo (San Vicente Island) fueled the economy. Combined with poor conditions at home, increasing cosmopolitanism for the first time encouraged a major exodus: Seafarers from the island of Brava joined western-bound whaling crews and, subsequently settled in RHODE ISLAND, CALIFORNIA, and primarily MASSACHUSETTS.

Cape Verde achieved recognition as a geocultural "broker" in the 20th century. In addition to building transportation facilities, Portugal established the islands as an educational center for its African colonies, with a seminary and secondary school. But the pervasive anticolonial movement sweeping the continent similarly inspired Cape Verdeans toward independence in 1975. All told, the islands' geographic position yielded a maritime economy descended from the Age of Exploration, and a unique Afro-Portuguese Crioulo (creole) culture that became better defined with the dissolution of colonialism.

## capitals

A CAPITAL IS A CITY or town that serves as the administrative center of a political unit such as a country, state, or province. The word *capital* is ultimately derived from the Latin word for "head" (*caput*). Capitals of counties in the UNITED STATES are generally known as "county seats"; in England and IRELAND such capitals are called "county towns." The term *capital* is sometimes used in a promotional sense to refer to an impor-

tant product closely associated with a particular city or town. For example, Gilroy, CALIFORNIA claims to be the “Garlic Capital of the World,” while Farmington, MAINE is the “Earmuff Capital of the World.” Most political units have a single capital city, but several cases of multiple capitals do occur. BOLIVIA’s constitutional and judicial capital is Sucre, while La Paz serves as the administrative capital. The legal capital of the NETHERLANDS is Amsterdam, although The Hague functions as the governmental center. SOUTH AFRICA maintains three capitals: Pretoria (the administrative capital), Bloemfontaine (the judicial capital), and Cape Town (the legislative capital). Two U.S. states once maintained dual capitals. CONNECTICUT’s capitals were New Haven and Hartford; in the interest of efficiency, Hartford was made the sole capital in 1875. RHODE ISLAND’s capitals were Newport and Providence; Providence has been the sole capital since 1900.

Geographers sometimes distinguish between “natural” capitals and “artificial” capitals. Examples of natural capitals would be LONDON, PARIS, and MEXICO CITY, cities that dominate their countries. Historically, it was often the case that the country, or the nation, took shape from these natural capital cities outward. Artificial capitals are those that were founded by their political units specifically to serve as capitals. Examples include Canberra in AUSTRALIA, Brasilia in BRAZIL, and recently Abuja in NIGERIA and Dodoma in TANZANIA. The distinction between natural and artificial capitals is not a precise one, as all capitals were at one time chosen to fill that role. Paris, for example, became the permanent capital of FRANCE in the year 987 when Hugh Capet, who had been Count of Paris, assumed the French throne.

Many capitals have been chosen because of the perceived advantages of their location. Some governmental units have placed their capital cities at the center of their area, or perhaps at the center of their population. Indianapolis and Springfield were chosen as capitals of INDIANA and ILLINOIS in the early 19th century because those cities were located near the geographic centers of their respective states. Since the northern portions of WISCONSIN and MICHIGAN were and are relatively unpopulated, Madison and Lansing lie much nearer to the center of population of their respective states than to the geographic center. Occasionally, though, a political unit will place its capital in a city perceived to be near the center of population, only to have the center of population shift radically over time. Examples include Sacramento, California, which was chosen as the capital in 1854 at a point midway between San Fran-

cisco and the goldfields of the Sierra Nevada. Today, with the largest part of California’s population located far to the south, Sacramento is an eccentric capital. FLORIDA continues to maintain its capital at Tallahassee, midway between the state’s major early 19th-century population centers, Pensacola and St. Augustine. Now, with the largest part of Florida’s population living in southern Florida, Tallahassee has become an off-center capital. Lying roughly midway between Australia’s two dominant cities, Canberra was chosen as the national capital following Australia’s unification in 1901, since neither Melbourne nor Sydney would allow the national capital’s functions to go to the rival city.

Other capitals have been chosen as compromise locations, balancing competing interests within their political units. Ottawa, for example, lies not only along the border between CANADA’s two largest provinces (Ontario and Quebec), but more importantly alongside the cultural divide between French and English Canada. The early United States government chose Washington, D.C., as the national capital, located at a point neither too far south nor too far north, along the Potomac River on the MARYLAND-VIRGINIA border.

When the American Civil War broke out, Washington found itself precisely on the border between the loyal Union states and the seceding Confederacy. Arlington Memorial Bridge across the Potomac now symbolically re-joins the South to the North, linking the Lincoln Memorial on the north or District of Columbia (D.C.) bank with Arlington House (the home of General Robert E. Lee) on the south or Virginia side.

Historical geographer Vaughan Cornish has argued that expanding states tend to locate their capitals, not in the center of their area or population, but rather off-center, toward their most dynamic frontier. JAPAN, for example, moved its capital northeastward from Kyoto (“capital city”) to Tokyo (“eastern capital”) in 1868 at the same time that the Japanese were expanding their control over the northern half of the Japanese archipelago.

Berlin became the dominant German capital, located toward the frontier where Germans were pushing eastward against Slavic and Baltic peoples. After the American Revolution, the capitals of seven of the original 13 states were transferred away from coastal cities and reestablished in the interior. Incidentally, these seven states—NEW HAMPSHIRE, NEW YORK, PENNSYLVANIA, Virginia, NORTH CAROLINA, SOUTH CAROLINA, and GEORGIA—were precisely those states that possessed an open frontier to their west.

## Caribbean Sea

THE CARIBBEAN SEA is a suboceanic BASIN in the western ATLANTIC OCEAN. The sea covers just over 1 million square miles (2.6 million square km) and contains numerous islands. The islands, which vary greatly in size, cover some 91,000 square mi (235,688 square km). CUBA is by far the largest at 44,000 square mi (113,959 square km). In contrast, ANGUILLA has a mere 100 square mi (259 square km).

The islands can be divided into four groups. First are the BAHAMAS, consisting of more than 700 small islands. Second are the Greater Antilles, made up of Cuba, Hispaniola, PUERTO RICO, and JAMAICA and comprising more than 80 percent of the total land area of the Caribbean. Third are the Lesser Antilles, comprising two arcs of islands. An inner arc is made up of volcanic islands, while an outer arc is made of coral limestone islands. Fourth are the South American offshore islands of ARUBA, Bonaire, Curaçao, TRINIDAD, and TOBAGO.

Several geographic characteristics define the Caribbean. One is the insular nature of the region. The fact that the region is made up of many small islands has shaped the Caribbean's history. The small size of the islands made it virtually impossible for the native inhabitants to resist European attacks, enslavement, and disease. The large number of islands allowed several European powers to colonize the region beginning in the late 1400s. The presence of various European countries has contributed to the cultural diversity of the Caribbean Sea. Furthermore, because of the fragmentation of the region, there was historically more interaction and contact between the islands and the metropolitan powers than among the islands.

The small size of the islands is a second important feature. While the islands are small, many of them have relatively large populations, making them some of the

most densely populated areas of the Western Hemisphere. The small size of Caribbean nations has led to numerous problems. Land is often scarce and internal markets are small, forcing countries to rely on imports. Per capita government spending in areas such as education, healthcare, and welfare is all extremely high in the Caribbean.

A third defining characteristic is the Caribbean's location in a maritime tropical air mass. Average temperatures in the region are high at around 80 degrees Fahrenheit. There is little seasonal change throughout the Caribbean. Precipitation in the region varies from island to island. Low-lying islands receive very little rainfall, while those with higher volcanic peaks receive more. Precipitation even varies on each island, as the northeastern sides tend to be wetter than the southern sides.

Hurricanes are a fourth characteristic of the Caribbean. They are a regular occurrence in the region, arriving between June and November of each year. The hurricanes form in the eastern Atlantic Ocean and follow the trade winds to the Caribbean, where an average of eight strike each year. Hurricanes are often destructive, damaging property and crops. In 1963, Hurricane Flora took more than 7,000 lives in the Caribbean.

A fifth characteristic is environmental degradation. The introduction of export agriculture in the form of sugarcane production ushered in environmental problems in the Caribbean. As European plantation owners put their African slaves to work clearing forests, native flora and fauna often disappeared. Such deforestation led to problems such as increased risk of erosion and drought. Fertile soil was quickly exhausted. By the 20th century, poverty and tourism both contributed to these environmental problems in the Caribbean.

A sixth feature of the Caribbean is its strategic location. It serves as a link between Europe and Latin America. The Spanish used the Caribbean as a base to conquer the mainland areas of the Americas. Beginning in the late nineteenth century, the UNITED STATES began to become involved in the Caribbean because of its strategic importance. After the opening of the PANAMA CANAL in the early 20th century, the region's strategic significance for military and economic matters greatly increased.

### CARIBBEAN HISTORY

The history of the Caribbean gives the diverse region a sense of common identity. The islands share a common history of conquest, colonization, slavery, and sugar

plantation agriculture. Before the arrival of Europeans in 1492, there were a series of cultural waves from the mainland of the Western Hemisphere to the islands of the Caribbean. Two major indigenous groups populated the region. First were the Arawaks, a largely peaceful group who inhabited the larger islands. Second were the more warlike Caribs, who concentrated on smaller islands.

The period from 1492 until the mid-1600s was one of European conquest and colonization. The Spanish were the first Europeans to settle the Caribbean, concentrating on the island of Hispaniola. They then moved on to other islands such as Jamaica, Cuba, and Puerto Rico in search of gold and slaves. The native population of the Caribbean was unable to withstand this Spanish conquest. Both gold and slaves were quickly exhausted and the Spanish turned to the conquest of the mainland.

By the mid-17th century, other European powers such as the British, French, and Dutch became increasingly involved in the Caribbean. It was in this period that sugar and slavery came to dominate the Caribbean. At this time, the Caribbean more fully became part of the Atlantic economy. British and French colonies such as Barbados, Jamaica, and Saint Domingue became major sugar producers. Large plantations came to dominate the Caribbean landscape. Increasingly, Europeans turned to African slave labor to work these plantations. Of the approximately 10 million African slaves forcibly transported across the Atlantic Ocean between the 15th and 19th centuries, about half went to the Caribbean.

A number of trends have marked Caribbean history since the 1800s. A modern plantation system replaced the slave-based one. Most islands achieved political independence. Many Caribbean nations have since attempted to diversify their economies through industrialization. Since World War II, tourism has come to dominate the region.

## ECONOMY

Overall, the Caribbean economy is small, dependent on trade, and not very diversified. In general, the region produces a limited number of primary products, while importing most of its manufactured goods. Due to its dependence on international trade, the Caribbean often suffers through periods of boom and bust. Unemployment is a major problem that plagues many islands. Much of the region's export earnings must go to service debt, limiting economic growth. Furthermore, the Caribbean is largely dependent on North American

and Europe for markets, technology, investment, and credit. Agriculture in the Caribbean is still important, although it is declining. Soil exhaustion, the high cost of fertilizers and pesticides, and international competition harm the region's agricultural industry. Large plantations produce cash crops for export on many islands. There are also a large number of peasants who produce for local consumption. Caribbean agriculture is often supported through preferential trade agreements, especially with former colonial powers. Sugar remains the key crop in the Caribbean, although its importance is declining as a result of high production costs and world competition. Bananas are another important crop, as they receive preference in many European countries over cheaper Central American bananas. Tobacco and coffee are other significant agricultural products grown in the Caribbean.

The illegal drug trade plays an important role in the Caribbean. Some islands such as Jamaica are important producers of marijuana. Furthermore, narcotics traffickers often ship drugs such as cocaine and heroin through the Caribbean on the way to the United States.

Mineral resources are important on a number of islands. Cuba and the DOMINICAN REPUBLIC produce significant amounts of nickel. Bauxite, needed for the production of aluminum, traditionally was an important raw material in Jamaica, HAITI and the Dominican Republic. Trinidad possesses important oil and gas reserves.

There have been some attempts to industrialize in the Caribbean. Some countries have implemented import substitution industrialization policies in order to produce goods that were once imported. Others have emphasized export-oriented industrialization in order to attract foreign companies. There are numerous small plants in the Caribbean, such as breweries and cement works. Some islands also have important refineries for bauxite, sugarcane, and petroleum.

Since the 1960s, there have been attempts to integrate the economies of the Caribbean. In 1973, 13 former British colonies created the Caribbean Community and Common Market (CARICOM) to improve international bargaining power. Other countries later joined. Overall, CARICOM has had only limited success, although it has established the Caribbean Food Corporation and the West Indies Shipping Company.

Because of its sunny climate and recreational opportunities, tourism has become a major industry throughout the Caribbean. The region has become a popular winter vacation spot for tourists from the

United States, CANADA, and Europe. At about two-thirds of the total travelers, the United States sends the most tourists to the Caribbean, in large part because of the geographic proximity of the region. Ironically, transportation and communication between the Caribbean and the tourists' home countries is better than that among the Caribbean islands.

Before World War II, few U.S. tourists frequented the Bahamas and Cuba. Large-scale tourism in the region began in the 1960s. The governments of most Caribbean islands actively promote tourism, presenting their countries as island paradises. The tourist industry creates jobs and helps the balance of trade in the small Caribbean nations.

There are a number of important problems with the Caribbean tourist industry. Tourism relies heavily on other countries. Difficult economic times in the United States, for example, negatively affect tourism. Bad weather can also adversely influence the industry. While tourism does create jobs, the jobs are generally low-paying ones. Foreign companies, such as cruise lines, often benefit more than the local economy. Large-scale tourism can also harm the environment, straining the water supply and leading to problems of garbage disposal.

## cartogram

ONE OF THE LIMITATIONS of the traditional paper map is that real world areas with large populations are usually small in physical size and therefore represented as small area units on a map. As such, traditional paper maps have tended to mask geographic patterns in small area units that are of importance and interest on the map. The cartogram was developed to overcome this challenge.

A cartogram is a map or diagram that depicts attributes of geographic objects in direct proportion to the area or length of the objects. In linear cartograms,

the length (distance or travel time) of geographic objects is scaled in proportion to the attribute being mapped. Likewise, in area cartograms, the area of a geographic object is scaled in proportion to an attribute. For example, if an area cartogram uses the area of a country to depict the magnitude of its population (the attribute), then country A, with twice the population of country B, will be represented on a cartogram with an area twice that of country B. Since the cartogram does not represent geographic space, but alters the size of objects in proportion to an attribute, it is not considered a scaled map. As such, the cartogram does not always appear visually similar to a map.

Cartograms are of three types: noncontiguous, contiguous, and Dorling cartograms. Noncontiguous cartograms are the simplest and allow the geographic objects to be detached from their adjacent neighbors. This detachment permits the objects to expand or contract their area without distorting their natural shape. Contiguous cartograms are more difficult to construct because neighboring objects must remain in contact, resulting in a distortion of shape.

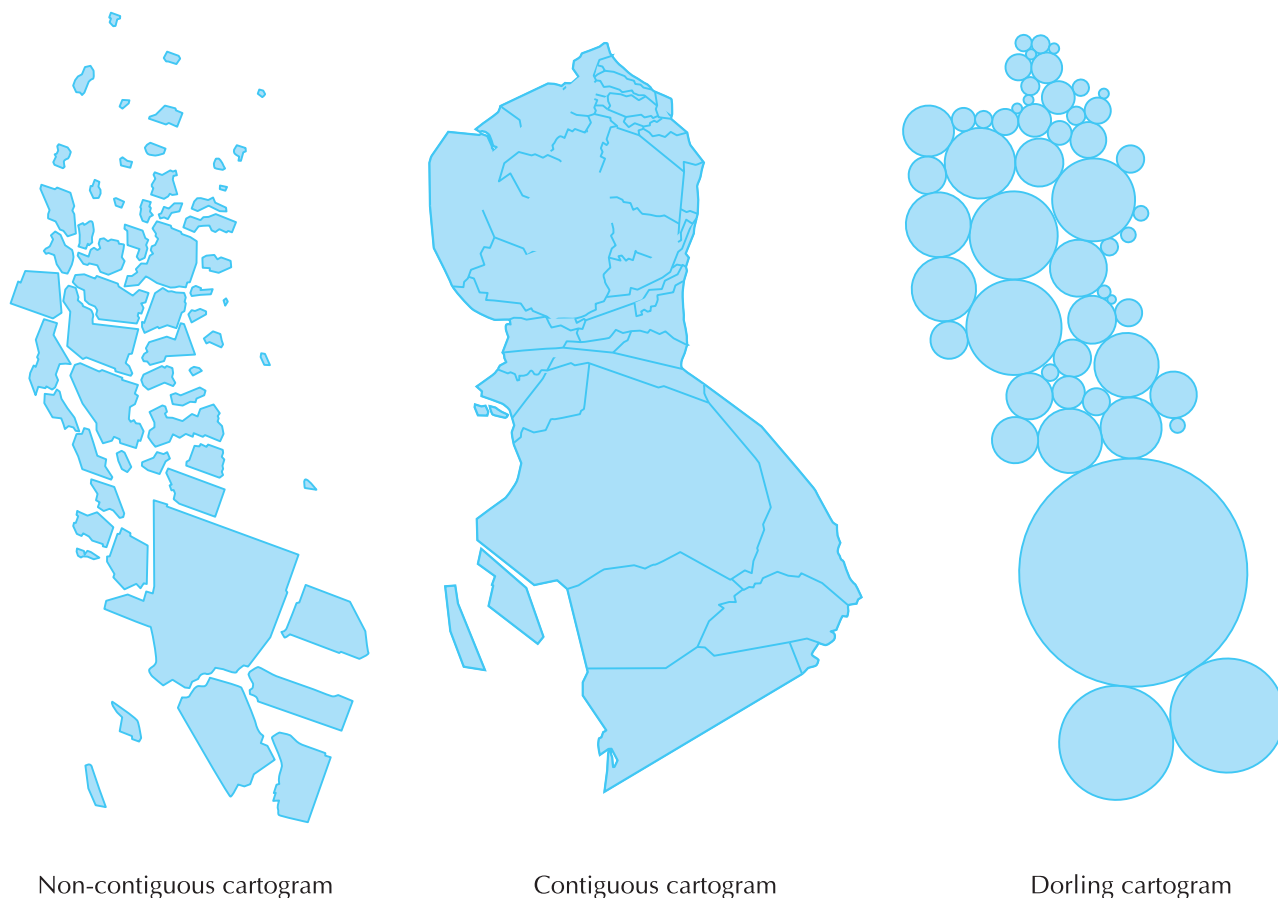

In Dorling cartograms the geographic objects are replaced with a uniform nonoverlapping shape, such as a circle, where the area of the circle is proportional to the attribute being represented. Each cartogram type presents the attribute of geographic objects from a different perspective. Also, each type of cartogram requires a different level of effort from the reader to understand the structure and content of the information being communicated.

In addition to the three pure forms of cartograms, there exist pseudo-cartograms, or false cartograms. Pseudo-cartograms do not strictly follow certain cartogram rules. For example, instead of enlarging or shrinking objects directly, Waldo Tobler pioneered an approach where the distance connections between the objects are transferred to a reference grid such as latitude and longitude to maintain directional accuracy among the objects. But in so doing, extensive errors are created in the real object size. However, pseudo-cartograms are useful because they are regarded as an intermediate stage that is easily created by a computer and can be later modified by a cartographer toward the development of a pure continuous cartogram.

Initially, cartograms were constructed manually using traditional map-making tools and techniques. But this is a tedious and time-consuming process. Today, the cartogram construction process is accomplished predominantly by computer software programs. The usefulness of a cartogram lies in its ability

Three different cartogram forms showing the population of California by county.

to communicate and visualize data and information. The downside is that each map message will require the creation of a new cartogram, and during the cartogram creation process, data loss is inevitable. However, a well-designed cartogram can communicate information visually and make it much easier for the public and uninitiated reader to understand intended messages. As a scientific tool, cartograms facilitate the visualization and analysis of geographic patterns by clearly emphasizing attributes of interest.

## cartography

A TERM DERIVED from the word for chart (*charte*) or drawing, cartography is traditionally defined as the art and science of making maps. But over the years, a great deal of theoretical and practical research has been done in all aspects of the subject, including work on map projections, map designs, map visualization, cartograms, terrain models, and the incorporation of new

computer-based technologies such as geographic information system (GIS) data and remote sensing images into the map-making process. These research and technological developments have increased the utility of cartography for services such as geographic data display, storage and analysis, communication, planning, and decision making. At present, the International Cartographic Association defines cartography as the art, science, and technology of making maps, together with their study as scientific documents and works of art.

An understanding of general cartography trends can proceed along two interconnected pathways. In the first pathway, the emphasis is usually on the finished map product together with evaluations about the map functionalities, techniques used, symbology, and aesthetics. In the second pathway, the emphasis is on the data-surveying and compilation aspects of the mapping process. Historical maps and their presentation as graphical objects such as atlases and sheet maps are characteristic of the first “map product” pathway. Later, the integration of information and communication technology (ICT) into mapping and the inevitable data generation and processing consequences have come to define the “data compilation” pathway. In this second pathway, the impact of the mapping process on the map output is the major focus of study.

## THE STUDY OF MAPS

The modern study of maps always originates with a description of how maps work. All maps are about spaces and places that are represented by shape, area, distance, direction, and location in a graphical medium. The surface of the Earth is not a flat plane, so a modification is required to transform the positions of places on the curved earth to the flat sheet of the map so that distortions in shape, area, distance, direction, and location are minimized. This process is called map projection, and the transformation is governed by rigorous mathematical rules.

The projection process takes the lines of latitude and longitude of the round earth and arranges them on a flat plane as a uniform grid. These grids, together with a scale that links the relative linear proportions of the round earth and its representation on the flat plane, allow the map space to be structured so that map properties can be determined to a high level of accuracy. Some examples of projections include the Mercator and Robinson projections.

The scale of the map determines the level of detail that can be shown. Maps of a large scale show more detail with greater accuracy. As the map scale becomes

progressively smaller, larger swaths of geographic areas are shown and so features on the map must be generalized to avoid congestion. The generalization procedure involves stages of simplification, selection, enlargement, displacement, and merging. Simplification involves the progressive collapsing of map features from area to line to point representation as scale decreases. As an example, a lake may be represented as an area at one scale but as a point at a smaller scale. Selection attempts to retain features that are important given the goals and uses of the map. However, some of these important features might not be clearly visible at the desired scale, and so enlargement artificially distorts their dimensions to enhance visibility. Displacement shifts overlapping features so that they become separate elements and more clearly identifiable. Merging aggregates multiple features into simpler ones to correct map overload that can arise from too much detail.

The mapping process also includes the symbolization of the real world using a standardized graphical language. The symbols used have dimensions—point, lines, areas, volumes, and duration—and can be distributed in a discrete, continuous, or sequential manner to communicate feature patterns. Lettering and text labels also form an important part of the feature encoding process. Information about each feature, such as type of road or population, is encoded using variations in nine graphic variables. The graphic variables are size, shape, orientation, color value, color intensity, level of grayness, texture, focus, and arrangement. These graphic variables, together with strict rules for their use, allow the cartographer to encode and distinguish the many features on the spherical real world unto the flat map.

Cartography demands a diverse mixture of scientific and artistic skills to produce effective maps. Cartographers are visually oriented individuals with a talent for communicating with drawings, symbols, and graphics. They attempt to balance rigorous scientific methods with artistic elegance to communicate an accurate, appealing, and easily understandable message through the map medium. However, simply combining all the map elements does not guarantee an effective and aesthetically pleasing map. The challenge then is to understand what constitutes a good map.

A list of qualities that could characterize excellence in statistical graphic designs was proposed by Edward Tufte in 1983. This list was viewed by cartographers as important because if applied to maps it would emphasize the importance of the perceptual qualities of the map design rather than the individual map compo-

nents. Key principles to emerge were that a visual organization of images and a hierarchy should guide the map design between different visual levels. These design principles, together with the artistic abilities of the cartographer, can lead to a balanced, pleasing map.

Computer technology has also influenced cartography in many ways. The use of computer software to automate the map design process has probably been the greatest influence. However, with these improvements in efficiency come new challenges. Selecting the best software for the mapping task and using the software effectively has become one of the main challenges. The proliferation of drawing and illustration software packages has only served to intensify the challenge. Computer literacy is also a cause for concern because many software packages require some knowledge of computer systems operation. Other challenges include paper to digital map conversion accuracies, complexity of data to be presented, output medium, and the future usability of digital data derived from the conversion process.

## GIS AND RS

Geographic information systems (GIS) and remote sensing (RS) have established a beneficial synergy with cartography. Although these technologies have been around since the 1960s, it is only in the last 10 years or so that a stronger link was established with cartography. A GIS is a collection of computer hardware, software, and trained personnel designed to capture, store, manage, manipulate, and communicate data that is spatially referenced. Remote sensing is the gathering of information related to the Earth's surface and does not involve contact with the object under study. RS techniques include aerial photography, radar, and satellite imagery.

Usually remote sensing is accompanied by some "ground truthing," where the researcher visits multiple areas to make sure that the images being received are interpreted correctly. These new digital tools have aided the production of maps. While some maps are still hand-drawn, many more are produced through the analysis of GIS data sets and overlay operations, and digital image processing and classification. Current GIS and RS software now support mapping modules that allow the flexibility and functionality to produce good map products.

Well-known GIS software includes ArcView, ArcGIS, MapInfo, and ArcInfo; ER-Mapper, IDRISI, and ERDAS Imagine are equivalent digital image processing software. An important concept that permeates GIS

and RS software is that of raster and vector data processing capabilities. Raster data store the real world as grid cells where each cell represents some attribute on the Earth's surface. Vector data store the real world as a collection of points, lines and areas. While it is relatively easy to convert between the raster and vector data forms, the cartographic approach has been to select one data form most appropriate for the project goals and to use it consistently throughout the project.

However, despite their advanced functionalities, GIS and RS software still do not yet allow cartographers the flexibility to go beyond the creation of an electronic version of the paper map. This is maybe due to software business strategies that minimize GIS and RS software complexity to maintain broad-based end-user adoption. Ultimately the customization of the final map product is completed by illustration and drawing software packages such as Adobe Illustrator and Macromedia FreeHand. The integration of GIS and RS has provided new ways to visualize data in search for new map patterns and trends that can support analysis and decisions. The role of cartography in the synergy is to guide the development of "good mapping" products for multiple uses and users.

The rapid evolution of the internet and its impact on cartography have been another area of excitement and new opportunities for cartographers. The internet and world wide web (web) are a distributed collection of multimedia information networked together. Access to this information resource is through a browser such as Internet Explorer and Netscape. Of importance to cartographers is the use of the web to enhance, access, and deliver map products. The first wave of enhancements in multimedia cartography improved the static digital map by integrating features such as video, audio clips, and animations to present information in a more integrated manner.

The current wave of enhancements is termed web-GIS, internet-GIS, or web-based mapping and addresses issues such as data democratization and end-user analysis capabilities. The mapping products delivered to end users can range from a simple static digital map to a completely immersive and interactive mapping environment in which to explore and navigate the digital map space. Despite the rapid progress in multimedia cartography and web-GIS, there are still a number of challenges to overcome with the use of the Web in cartography. These challenges are directly related to the data used and incorporate research issues such as standards, interoperability, quality, confidentiality, copyright, and individual privacy.

Today, traditional cartographic principles have been continuously adapted to a variety of user needs and technological changes but still form the core of many digital mapping projects. The Internet holds the key to the continual evolution of cartography. This is so because the Internet integrates both cartographers and noncartographers to communicate, use, and analyze maps, all of which raises awareness of and competence in digital mapping products. The proliferation of digital data on the Internet has also made it relatively easy to produce digital maps.

Students can best prepare for the future of cartography by keeping up to date with new technologies such as GIS, RS, and spatial data analysis. A lack of relevant training in these areas has been cited as the primary source for poor mapping products, especially since software products are now readily making mapping functionalities available but with little or no guidelines for effective map design. Another aspect of relevance to good map design is color choice and selection. While color theory is well developed for paper maps, there is not much systematic knowledge about color choice and use in an electronic medium.

## Caspian Sea

THE CASPIAN SEA IS ONE of the world's largest bodies of water, situated in a depression between RUSSIA, KAZAKHSTAN, TURKMENISTAN, IRAN, and AZERBAIJAN. It is unique among the world's inland seas in that it is completely isolated from the rest of the global ocean

and has a distinctive continental climate which gives the area extremes in temperature, from very hot summers to very cold winters.

Several rivers flow into the Caspian Sea, most notably the VOLGA and the Ural in the far north and the Terek, Sulak and Kura rivers from Daghestan and the Caucasus to the west. In fact, by including the entire Volga River Basin, the Caspian has the largest catchment area in Europe (1.4 million square mi or 3.5 million square km). But no rivers flow out of the Caspian, and most of the water is lost through evaporation. This is aided by the fact that much of the Caspian is very shallow, particularly in the north and the east. These parts are also very low-lying: The lowest point in Europe is the surface of the Caspian Sea, 89 ft (27 m) below sea level. Most of the eastern coast of the Caspian Sea is dry, with the extreme southeastern corner leading directly onto the Kara Kum Desert. In contrast, the southern and western shores are more steep, culminating in the nearly vertical walls along the southern coast where the ELBURZ and Talysh mountains of Iran come down to the sea. The seafloor drops most dramatically in this region as well, with the Caspian's greatest depths over 3,300 ft (1,000 m). The southwestern areas are also mountainous, consisting of the easternmost reaches of the CAUCASUS mountain ranges.

The Caspian stretches for over 620 mi (1,000 km) from north to south, and between 125 and 250 mi (200 and 400 km) east to west, totaling 143,270 square mi (393,000 square km) in area. It holds much of the world's lacustrine (lake-associated) water: 18,881 cubic mi (78,700 cubic km) of mixed salty and brackish fresh water. The salinity of the Caspian is heavily dependent on the level of flow from the Volga.

### WORLD'S CAVIAR SUPPLY

Sea life in the Caspian has mostly been cut off from other marine populations for millions of years, though recently there has been some colonization of Mediterranean species via the Don-Volga Canal. Most famous of the Caspian fish are its sturgeon (90 percent of the world's catch), prized for their caviar.

The Caspian is also home to large populations of seals, which are also hunted for their furs. The Caspian was the first place to begin marine extraction of oil and is now one of the most carefully examined regions of the world for future potential in oil and natural gas, particularly in the sandy lowlands and the Mangyshlak and Cheleken peninsulas along the eastern coast.

The eastern coast is marked by several deep inlets and bays, most of which are very shallow. When wa-

Most famous of the Caspian fish are its sturgeon (90 percent of the world's catch), prized for their caviar.

ters from these bays evaporate, significant valuable chemical compounds are left behind. The world's largest deposits of sodium sulfates are in the basin of the Kara-Bogaz-Gol Bay in Turkmenistan. This bay is considered the world's largest lagoon, as it is mostly cut off from the main body of water by sand bars.

At the height of the Soviet era, this seal was made complete and the bay completely disappeared (a disappearance of several thousand square kilometers of water). But extraction of chemical compounds was actually made more difficult than envisioned, and since the 1980s, the project has been reversed, and water is returning to Kara-Bogaz-Gol. Soviet Volga dam projects significantly lowered the levels of the Caspian in general from the 1930s to the 1970s, when environmental damage became too great to continue to be ignored. The Caspian also suffers from pollution, primarily close to industrial centers and oil refineries along the Apsheron Peninsula of Azerbaijan, and its major city, Baku. Other major ports include Astrakhan, Derbent, and the former Soviet naval station at Krasnovodsk, now in Turkmenistan. The most significant Iranian port on the Caspian Sea is the town of Bandar-e Anzali, the center of the Iranian caviar producing industry.

## Catholic Church

SINCE THE BEGINNING OF Christianity, the extension and growth of the Catholic Church were a means to explore, map, and discover the world. Explorations were the first step in establishing missions in foreign lands, the cause of great travels around the globe. The Acts of the Apostles, and also ancient and medieval legends, tell about the missions of the apostles and first disciples in the ancient world (Paul in MALTA and Rome, Peter in Antioch and Rome, John at Patmos in the Greek islands, and the legendary presence of Thomas in INDIA, James the Elder in SPAIN, Joseph of Arimatea in England and Mary Magdalene in FRANCE, among others).

Southern Europe, part of Southwest Asia and North Africa were the first places where the new Christian religion propagated. The great moment of the Christian expansion was the Constantine Edict in 313. From then on, Christianity became the official religion of the Roman Empire. This was the start of an alliance between the church and political power that had a great impact on the diffusion of the Christian religion in the ancient world. Charlemagne gave to his Holy Roman Empire a religious mark and contributed to Christian social defense and expansion. The Byzantine Schism in 1054, separated from the Catholic Church the great part of the Christians of eastern Europe and Asia, from then on called Orthodox.

With the start of new religious orders in the 13th century (mainly Franciscans, Dominicans, Servants of Mary, Trinitarians, and Mercedarians) and with the organization in religious orders of groups of hermits (Augustinians and Carmelites), the missions had a great push. Thanks to the Franciscan John of Pian del Carpine and Odoricus of Pordenone, Christianity was preached for the first time in CHINA. The new religious orders were also leaders of the expansion of Christianity in America after the Christopher Columbus voyage. With the work of Dominican Bartolomé de Las Casas,

Native Americans were accepted as human beings and evangelized. After the separation of part of Christianity from the Catholic Church in the age of Reformation (16th century), Catholicism lost its influence in a great part of northern and central Europe, especially in GERMANY, England, SCOTLAND, a result of the principle "*Cuius regio, eius religio*" ("the religion of the prince has to be the religion of his people"). The church reacted to the reform of Martin Luther in France, John Calvin in Switzerland, and Henry VIII in England with the Council of Trent and founded new religious orders (Jesuits, Lazarists, etc.) nearer to the pope and less attached to monastic life. The rule of the missions of the Jesuits in India, JAPAN, South America, and CANADA has been very important since then.

In 1622, the Congregation of Propaganda Fide was created as the Roman department that had the direction of the Catholic missions. In the 19th century, a great role in the evangelization of America and Asia was played by Lazarists and Oblates of Immaculate Mary, a religious order founded by the bishop of Marseille, Eugenio de Mazenod. In this century, Oceania had its first catholic preacher in Peter Chanel, a French priest martyred in 1841 in Futuna, and Africa had great missionaries such as Daniel Comboni, founder of the Combonians Missionaries, and the Cardinal Lavignerie, founder of the order of the White Fathers.

With the leadership of Pope Pius XI, Catholic missions had a strong influence in the first half of the 20th century, and in the second half, mainly after the Vatican II Council (1962–65), the Catholic hierarchy was extended to a great part of the world.

### CATHOLIC CHURCH AND POLITICAL POWER

The Catholic Church had a very important role in the political history of the world. The Pontifical State, created in the first middle age (the first authentic document of pontifical sovereignty dates back to the 8th century), survived until 1870. The pope was the supreme authority of this state, which across the centuries had a different extension: For a long time, it ruled a large part of central ITALY, but since 1861 only the Lazio region has been under its rule. After the union of Italian kingdoms, the pope fought against the Italian government, and only in 1929 was there the Conciliation, a pacification act signed by the Italian premier at the time, Benito Mussolini, and the first minister of the Holy See, Cardinal Peter Gasparri (for Pope Pius XI). With this act, the new state of the VATICAN CITY was born, under the power of the pope, and at this time the Holy See recognized the Italian king-

dom. The Holy See has today separate diplomatic relations with the great part of the nations of the world.

The Pope is not the only Catholic bishop who had sovereignty. In the past, the bishop-prince of Trento, in northern Italy, was important, and the bishop of Urgel, in Spain, is also today one of the heads of state of ANDORRA. Also Catholic religious orders had sovereignty: Missions of Jesuits in Latin America, before their suppression, were a sort of independent republics. The Knights of Malta, a religious and military order, were sovereign in the islands of Rodi and Malta, and also today they have the sovereignty over the Knights of Malta palace and Church of St. Mary of the Priorate in Rome, and besides have embassies in a great number of nations in the world.

The Holy See prefers, in modern times, to have a regulation of relations with nations through special agreements called concordats. The first modern concordat was with Napoleon I in 1801, and today the Catholic Church has concordats with a majority of the nations in the world. In a lot of countries, there are modern political parties that declare their Catholic inspiration, but rarely does legislation adhere to the strictest tenets of the Catholic ethic, such as the prohibition of procured abortion, divorce, and artificial contraception.

### INFLUENCE OF CATHOLICISM ON GEOGRAPHY

Catholicism left a great imprint in the culture and way of life in many different parts of the world. Since the first times of Christianity, the enculturation of the new religion with the old culture was a prime effect. Greek and Roman culture, and culture of northern Europe, slowly integrated with Catholicism, with the substitution of the cult of the pagan gods with the cult of the saints. In time, almost everything in society had a special imprint by the religious Christian and Catholic culture.

One example is toponymy, the naming of places: In Europe and America, a great number of the names of places remember Catholic feasts, saints, and personages. CALIFORNIA in the United States remembers the work of Franciscan missionaries in cities such as San Francisco and LOS ANGELES (the latter named after Sancta Maria de los Angeles, the place near Assisi where Francis died in the 13th century), San Bernardino, San Diego (names of Franciscan saints). Corpus Christi, TEXAS, commemorates the Catholic dogma of transubstantiation, and the great number of places called St. Mary or Santa Maria are surely an ef-

fect of the Catholic devotion to the Virgin Mary. A great number of places have names of Catholic saints: Santa Catalina, St. Helen, Santa Anna, mainly in the places where Catholic missions had a important role in the exploration and foundation of new towns and villages. Another important effect is the diffusion of the names of Catholic saints among the newly converted people; this happened in the past and continues today.

Works of art, but also the life of the everyday, were inspired often by Catholicism: towns built around Catholic shrines (Loreto in Italy) or developed nearby (Lourdes in France, Fatima in PORTUGAL, Pompei and San Giovanni Rotondo in Italy). The great cathedrals built everywhere in Christendom were the centers of towns and communities. Religious orders, mainly Jesuits and Dominicans, that collaborated in the past to found very important cultural institutes, have today evolved into preeminent universities and colleges around the world. Other religious orders have hospitals, mainly in Africa and Asia. All this is not to mention the Catholic calendar feasts that have become common holidays (holy days) in many nations around the world.

### CATHOLIC CHURCH IN THE WORLD TODAY

The Catholic Church today is present everywhere in the world, with 1.1 billion baptized Catholics, comprising 17.3 percent of the entire world population (16.77 percent of that population in Africa; 62.71 percent in the Americas; 2.89 percent in Asia; 39.96 percent in Europe; and 26.77 percent in Oceania). It is locally structured in 7,726 dioceses.

In Europe, the Catholic presence is very strong, mainly in Italy (227 dioceses), IRELAND (26 dioceses), Spain (71 dioceses), PORTUGAL (21 dioceses), POLAND (45 dioceses), BELGIUM (9 dioceses), Malta (2 dioceses), and France (98 dioceses). In the Irish Republic as in Italy, the feeling of being part of Catholicism is one with national patriotism. In Ireland, the long dominance of the British government and the imposition of Anglicanism as a national religion led Catholicism to be identified in Irish minds as a national resource. In Italy, the presence of the pope and the difference of culture and way of life between the north and south turned Catholicism into a traditional, common cultural heritage for the Italian people.

France has a great religious tradition, evident today in the popular shrines as Lourdes, St. Therese of Lisieux, St. John Vianney of Ars, but this tradition has to live together with a strong state laeity, coming from the liberal ideas of the French Revolution and Enlight-

enment. State and church are completely separated today in France, and this has also some consequence on education, with laws that forbid any symbols of religion (whether Catholic or Islam) in state schools. The Catholic Church in Belgium has to fight the secularization of culture, but it also has important centers of Catholic culture, such as Lovanio Catholic University and the ancient Society of Bollandistes in Brussels, the most important institution to study hagiography.

Spain has an ancient and strong religious tradition, as the Holy Week religious manifestations, mainly in Seville, and the famous shrine as Santiago de Compostela testify, but today some scholars point to a decadence in religious practice. Portugal has its religious center in the shrine of Our Lady of Fatima, one of the most visited in the world, and also has a great popular Catholic devotion. In the other nations of northern Europe, except Northern Ireland, where political problems involve too much religion, the ecumenical movement is very developed, and Catholics are in good stead with the other separated Christian churches (various Protestant denominations).

In the nations of eastern Europe, the Catholic rapport with the Orthodox Churches is good; only in RUSSIA are there problems with the Orthodox hierarchy, but the situation is getting better. In 2004, the restitution of the icon of Our Lady of Kazan by Pope John Paul II to the Russian Patriarchate of Moscow helped this pacification process. The same pope, John Paul II, was one of the protagonists of the new Poland, after the fall of communism, and Poland today is still a nation with strong Catholic traditions, as evidenced in the popularity of the national shrine of Our Lady of Czestochowa. In AUSTRIA (12 dioceses), there is a demand for a renewal of Catholicism, opposed by the hierarchy. SWITZERLAND (8 dioceses) is only partly Catholic, but it gives to the Holy See the soldiers for the small army of the pope, the Swiss Guard. Also relevant are the Catholic communities in Great Britain (32 dioceses), Germany (29 dioceses), NETHERLANDS (8 dioceses), LITHUANIA (8 dioceses), LATVIA (4 dioceses), ESTONIA (4 dioceses), UKRAINE (20 dioceses), CROATIA (16 dioceses), ROMANIA (12 dioceses), and HUNGARY (16 dioceses).

The presence of Catholics in Asia is mainly in the PHILIPPINES (86 dioceses), where the majority of the population are members of the Catholic Church. There are Catholic schools and universities, and Catholicism plays an important part in daily life.

In JAPAN (16 dioceses), the presence of Catholics is important, but it is a minority. There are Catholic

schools, and Catholic education is appreciated. Catholics of Japan have their own national shrine to celebrate St. Paul Miki and the others Japanese martyrs, patron saints of Japan.

In India (149 dioceses), the Catholic presence is small compared with the great number of inhabitants, but nevertheless important. The Malabaric Church dates back to apostolic times, and charismatic personalities, such as St. Francis Xavier and Mother Theresa of Calcutta, promoted Catholicism. SRI LANKA, thanks mainly to the missionary work of Joseph Vaz and Bishop Horace Bettacchini, has several catholic communities, with 11 dioceses.

In ISRAEL (2 dioceses) and PALESTINE (2 dioceses), Catholics live in small communities of Arab Christians, and are mostly related to the Franciscans Friars of Holy Land Custody, and other religious communities holding custody of the shrines of the Holy Land.

In SAUDI ARABIA and other nations where Islam is the official religion of the state, the presence of Catholics is restricted mainly to the chapels of foreign consulates. In some Islamic countries, there are ancient Catholic communities, such as the Chaldean Church in IRAQ (15 dioceses), or even new communities, such as the Church of Pakistan (7 dioceses). These parishes survive with great difficulties, often discriminated against by the majority.

In China, the Catholic Church had a very important presence (145 dioceses) before the Cultural Revolution in the 1970s. Today, Catholicism is restricted, except in HONG KONG. The government of China created a "Patriotic Church," a sort of Catholic Church separated from Rome, with the aim to bring Roman Catholics into the government-run version. In TAIWAN (13 dioceses), Catholicism is thriving, while in MONGOLIA, a small Catholic community is developing (1 diocese). VIETNAM (25 dioceses), South KOREA (18 dioceses), INDONESIA (37 dioceses), MALAYSIA (8 dioceses), LEBANON (24 dioceses), and SYRIA (17 dioceses) have a good number of Catholics as well, all within countries with majorities from other religions.

In Africa, Catholicism is growing, mainly in the center and in the south. The greatest problem of enculturation of Catholicism is still to be solved. For example, the Catholic people of RWANDA (9 dioceses) and BURUNDI (7 dioceses) cannot find a real peace after terrible tribal wars. The greatest Catholic shrines in Africa are the Church of Our Lady of the Peace of Yamossoucro in CÔTE D'IVOIRE (14 dioceses), the cathedral "Regina Mundi" of Port Said, in EGYPT (21 dioceses), the cathedral of Our Lady of the Help of Wau in

SUDAN (9 dioceses), the church of Our Lady of Africa of Algeri in ALGERIA (4 dioceses), and the Church of Our Lady of Maromby, in MADAGASCAR (20 dioceses).

Religious orders, such as Capuchins, Trappists, Combonians, Scalabrinians, and others have a large number of schools, universities, and hospitals in Africa. In KENYA (26 dioceses), the Catholic University of Western Africa is developing. Cults of local saints are encouraged by the Holy See with beatifications and canonizations, such as St. Charles Lwanga in UGANDA (20 dioceses), blessed Isidoro Bakanja and blessed Clementine Anuarite Nengapeta in CONGO (54 dioceses), and Iwene Michael Tansi in NIGERIA (49 dioceses). Other important Catholic communities are in ZAMBIA (10 dioceses), SOUTH AFRICA (27 dioceses), SENEGAL (7 dioceses), TANZANIA (30 dioceses), LESOTHO (4 dioceses), MOZAMBIQUE (12 dioceses), ANGOLA (16 dioceses), BENIN (10 dioceses), BURKINA FASO (12 dioceses), CENTRAL AFRICAN REPUBLIC (8 dioceses), CHAD (8 dioceses), and MALAWI (7 dioceses).

In North America, the Catholic presence is very active. In a place where most of the population comes from European origins, people have preserved their religions from their nations of origin. In CANADA (72 dioceses), most of French-speaking residents are Catholic. Echoing their counterparts in France and northern Europe, there is widespread devotion to St. Anne, who with St. Joseph dedicated the most important Catholic shrines of Canada, including the church of Notre Dame du Cap in Quebec.

## U.S. CATHOLICISM

In the UNITED STATES, Catholicism struggles to maintain its hold in light of the widespread scandal of priests accused of pedophilia. Many U.S. Catholics oppose the dictums and prestige of the Roman church hierarchy. Jesuits are devoted to schools and education. The national shrine for Catholics is the Church of Mary Immaculate of Washington. The United States has diplomatic relations with the Vatican, but not a concordat.

In the United States, there are some 18,400 members of religious orders (friars and nuns); Benedictine nuns number about 7,000. This great number of religious people, and the existence of local religious orders, such as the Sisters of the Blessed Sacrament for Indians and Coloured People, founded by St. Katharine Drexel in 1891, seem to portend a positive Catholic force in the United States.

Yet, despite these numbers, the number of Catholics in the United States has declined steadily since

1980. And there is a crisis of vocation, mainly in female institutions: American women do not like the secondary role that the Catholic Church reserves for women.

Catholic presence in Central and South America is very strong, a result of the heritage of Spanish and Portuguese colonization. Catholics have a good number of universities and schools, even if some nations have a laic state tradition. BRAZIL today has the greatest number of Catholic bishops and dioceses (266) in the world. Catholicism is sometimes mixed with ancient pagan cults, forming a very special way to practice the religion.

Great monuments testify to the Catholic faith of Latin Americans: The great statue of Christ on Corcovado (Rio de Janeiro in Brazil) is one of the more famous religious monuments in the world. The shrines of Our Lady of Guadalupe in MEXICO (125 dioceses), Our Lady Aparecida in Brazil, Our Lady of Lujan in ARGENTINA (70 dioceses), and Our Lady of Altagracia in the DOMINICAN REPUBLIC (12 dioceses) are very famous.

Also in the other nations of Latin America there are vibrant Catholic communities with their own traditions and devotions, such as St. Rose of Lima and St. Turibio of Mogrovejo in PERU (45 dioceses); Our Lady of Carmel in CHILE (27 dioceses), and others in BOLIVIA (18 dioceses), ECUADOR (24 dioceses), VENEZUELA (39 dioceses), COLOMBIA (75 dioceses), URUGUAY (10 dioceses), PARAGUAY (15 dioceses), GUATEMALA (14 dioceses), PANAMA (8 dioceses), HAITI (9 dioceses), COSTA RICA (7 dioceses), HONDURAS (7 dioceses), EL SALVADOR (9 dioceses), CUBA (11 dioceses), and NICARAGUA (8 dioceses).

A theological movement, called Theology of Liberation, has developed in the second half of the 20th century to address pervasive social problems of Latin America. The Vatican opposed the movement's political aims, particularly using violence to fight for the social needs of the poor, and its adherence to Marxist ideology.

Because there is a low number of priests in Brazil, a new catholic society called "Comunità di Base" has been created. In this society, a democratically elected lay person is the head of the religious community, hence allowing for the development of the Theology of Liberation. Sometimes, these poor communities are abandoned by the official Catholic hierarchy.

AUSTRALIA (32 dioceses) has a good number of Catholics, the great part descendants of emigrants from Italy and other nations with a Catholic majority. A very important religious and cultural center is the Benedictine Abbey and the town of New Norcia,

founded by Benedictine monks in the 19th century. A relevant Catholic presence is also found in NEW ZEALAND (7 dioceses) and in PAPUA NEW GUINEA (19 dioceses), where there is a great veneration for blessed Peter To-Rot, the first local resident to be beatified. The SOLOMON ISLANDS (3 dioceses) and the other islands of the Pacific (17 dioceses) have Catholic communities, too.

## Caucasus Mountains

THE CAUCASUS MOUNTAINS are the highest mountain range in Europe, but lie at the very eastern extremity of what geographers consider to be Europe. In fact, the dividing line traditionally used to divide Europe from Asia runs directly through the center of the range.

Forming both a barrier and a connector for civilizations between the BLACK and CASPIAN seas, and between the MIDDLE EAST and the STEPPES to the north, the cultures of the Caucasus region have occupied a central place for trade and cultural exchange for over 2,000 years. The range's isolated valleys have served as a haven for refugees and immigrants from many areas, resulting today in one of the most ethnically and linguistically diverse regions on Earth.

The two major ranges of the Caucasus, the Great Caucasus and the Lesser Caucasus, stretch east to west for nearly 550 mi (900 km) from the eastern shore of the Black Sea to Baku on the Caspian. Elevations generally rise from both ends towards the central range, in which the highest peaks are located, including Mount ELBRUS, the highest peak (18,506 ft or 5,642 m). The various ranges and subranges are similar in their mountain characteristics: jagged and generally impass-

able. Climatically, however, west and east differ dramatically, due to the effects of moisture off the Black Sea and the contrasting dryness of the Caspian. As a result, the western ranges tend to have a subtropical climate, with heavy vegetation, while the eastern part of the range is semidesert and barren. The Caucasus Mountains share many characteristics with the ALPS, but their peaks are generally much taller, averaging 6,000 to 9,000 ft (2,000 to 3,000 m)—over 20 summits are higher than Mont Blanc. Its ridges are mostly parallel, running from west-northwest to east-southeast, but are broken up by horseshoe-shaped ridges with glacier-filled basins. Many of these are unstable, subject to frequent landslides and avalanches. Most of the ridges are more continuous than those of the Alps, resulting in a greater barrier, with only one major pass—through the dramatic Daryal gorge—and several smaller ones that are usually obstructed by snow. As a result of several of these features, the Caucasus Mountains are generally more inhospitable than the Alps and have a more wild and austere quality.

The Caucasus ranges were formed in the same manner (and at roughly the same time) as the Alps, through tectonic plate collision between the Arabian Plate and the Eurasian Plate. This movement continues today, manifesting itself through regular earthquakes. Many years ago there was volcanic activity in the region, creating some of the tallest cones (like Elbrus), but these volcanoes are currently extinct, with the exception of the active mud volcanoes of the Apsheron Peninsula, which juts 53 mi (85 km) into the Caspian Sea. It is here where the most important of the region's natural resources are located—the offshore oilfields of AZERBAIJAN. Other oil resources are found on the northern slopes, near the cities of Grozny and Krasnodar. At the western extremity of the range, the Caucasus also extend a bit further than the land they occupies, forming the low mountains of the Taman Peninsula, which nearly joins with the Kerch Peninsula of the Crimea, across the mouth of the Sea of Azov.

The Great Caucasus range is divided from the Lesser Caucasus by a parallel valley, the Transcaucasian depression, averaging 60 mi (100 km) in width. This depression connects the Black Sea coast with the Caspian Sea, where elevations dip below sea level. The depression is divided in two by a low range perpendicular to the main ranges, the Surami, which forms the climatic barrier between the moist west and the dry east. To the west of this range lies the Colchis Lowlands, the “Riviera of the Caucasus,” with grapes and olives and holiday resorts. To the east lies the Kura

Lowland, dominated by the Kura River, the longest river in the Caucasus, which flows out of the Armenian Highlands, past the industrial city of Tbilisi to the Caspian Sea near Baku. Near its mouth, the Kura is joined by the Araks River, which starts in eastern TURKEY and forms the border of ARMENIA and Azerbaijan with Turkey and IRAN to the south. This basin was actually part of the Caspian Sea in times of higher water levels. Other major rivers of the Caucasus region flow north, cutting gorges through the Great Caucasus: the Kuban, which flows into the Black Sea, and the Terek and Sulak, which flow across Dagestan into the Caspian.

The Great Caucasus is itself divided into several ranges, the most important being the Main Range and the Front Range. The Main Range forms the drainage divide between north and south. A few kilometers to the north, the Front Range is less continuous, but has the highest peaks in the entire system (the extinct volcanic cones like Elbrus). To the north lies the Stavropol Plateau, which gradually slopes to the steppes of southern RUSSIA. Other prominent peaks besides Elbrus in the central section of the Great Caucasus include Dykh-Tau and Shkara, both just over 16,500 ft (5,000 m), and the slightly lower Koshtan and Kazbek. Mount Kazbek (also called Mkinvari) marks the easternmost part of the central range and is the second-most popular peak for mountaineers, after Elbrus. The eastern end of the range descends gradually toward the Caspian Sea, breaking up into isolated massifs rather than continuous chains. This region of low dry hills resembles the badlands of SOUTH DAKOTA. The Lesser Caucasus are less defined as parallel west-to-east ranges; instead they generally merge into the Armenian Highlands, and the Anatolian and Iranian plateaux to the south. Here the peaks are generally lower, 3,000 to 7,000 ft (1,000 to 2,000 m), and several of the elevated valleys have been filled in by volcanic material forming an elevated surface.

Three nations with completely different ethnic and linguistic roots dominate the southern slopes of the Caucasus (called Transcaucasia by Russocentrics, but more acceptably, the South Caucasus): GEORGIA, Armenia and Azerbaijan. Each of these has numerous ethnic minorities within its borders, many of which are currently embroiled in struggle for autonomy or outright independence, for example, Ajaris, Ossetians, and Abkhazians. North of the main range, Russians form the majority of the population (having settled there during the reign of Catherine the Great in the late 18th century) but also contend with separatist movements

of Caucasian peoples, notably the Chechens, Kabardians, and the many tribes of Dagestan. The crest of the Great Caucasus generally forms the border between Russia and the South Caucasian states, but their other borders are not as easily defined by the confusing knot of the Lesser Caucasus, resulting in several contemporary border conflicts, notably Nagorno-Karabagh, claimed by Azerbaijan and occupied by Armenia. Among the resources quarreled over are oil, which CHECHNYA has and Russia wants, and water, which Armenia has and Azerbaijan wants. Azerbaijan has access to the vast offshore reserves of Caspian Sea oil but needs the cooperation of Georgia to deliver its product to the West via pipelines to the Black Sea. Having achieved independence at the dissolution of the Soviet Union in 1991, much of the region still depends on Russia for electricity and other basic needs, despite its desire to reconnect ties both towards western Europe and the Middle East.

## Cayman Islands

THE CAYMAN Islands are one of the UNITED KINGDOM few remaining colonies in the CARIBBEAN SEA. The group, lying roughly 150 mi (250 km) northwest of JAMAICA, consists of three main islands, Grand Cayman, Little Cayman, and Cayman Brac. They were first named Las Tortugas by Christopher Columbus in 1503 because of the abundance of turtles, and turtles remain one of the chief natural features of the islands. Later, the islands were named for their other large reptile residents, *lagartos* (alligators), then *caymanas*, the Carib word for "crocodile."

The islands are low-lying limestone formations, surrounded by coral reefs, providing habitat for abundant marine life. Because the soil is so dry and thin, the islands have never been able to grow much agriculturally, and there are no rivers or streams. The islands are the tops of a submarine mountain ridge that extends

from BELIZE to CUBA. Parallel to the Cayman Ridge is the Cayman Trench, the deepest part of the Caribbean Sea—Bartlett Deep plunges over 18,000 ft (5,455 m). An abundance of healthy coral reefs draw numerous divers each year, particularly to the Bloody Bay Marine Park off of Little Cayman, one of the most diverse coral walls in the area. Cayman Brac and Little Cayman lie about 89 mi (144 km) northeast of Grand Cayman, and have a more varied topography, especially on Cayman Brac, with its high bluff, sheer cliffs, and caves. Grand Cayman is flatter and has a large, shallow reef-protected lagoon, the largest area of inland mangrove in the Caribbean. Almost all of the population lives on Grand Cayman. Little Cayman has almost no population but is home instead to nesting birds.

The Caymans formed part of the Spanish colony of Jamaica from the 16th century but were never settled and passed with Jamaica to the British crown in 1670. British presence was established mostly as a refueling station (for food and water provisioning), and the islands were administered as an appendage of Jamaica until that island's independence in 1962. Shark and turtle farming was the only economic activity until the development of tourism and finance in the later 20th century.

Today, the Cayman Islands are the fifth-largest offshore financial center in the world, employing most of its labor force and providing its residents with one of the highest standards of living and no direct taxation. In 1998 there were more than 40,000 companies registered in the Cayman Islands, including nearly 600 banks. Registration of ships and corporation brings in a large amount of government revenue. About 70 percent of the gross domestic product comes from tourism: More than 1.2 million visited in 1997, mostly from North America. A constant danger, however, lurks in the many Caribbean storms and hurricanes (cyclones)—Hurricane Gilbert, the most powerful storm recorded in the Western Hemisphere, hit the Caymans in 1988. A Category 5 storm, Gilbert's sustained winds of over 155 mi (249 km) an hour leveled nearly every structure on the islands.

## Central African Republic

**Map Page** 1115 **Area** 240,535 square mi (622,984 square km) **Population** 3,683,538 **Capital** Bangui **Highest Point** 4,658 ft (1,420 m) **Lowest Point** 1,099 ft (335 m) **GDP per capita** \$1,200 **Primary Natural Resources** diamonds, uranium, gold.

DEEP IN THE HEART of the African continent, the LANDLOCKED Central African Republic is on a heavily forested plateau about the size of TEXAS between the Chad and CONGO RIVER basins. It is bounded on the north by CHAD, SUDAN to the northeast, the Democratic Republic of the CONGO (formerly Zaire), CONGO to the south, and CAMEROON to the west. The area has a tropical climate with two annual wet seasons, May-June and October-November. However, in the very dry summer, the Harmattan, a hot, dust-laden wind blows in from the SAHARA DESERT with a saunalike effect in the cities.

From the 1500s until the 1800s, the area was ravaged by the slave trade. In 1894, the French occupied the region, then called Oubangui-Chari, and combined it administratively with Chad, GABON, and the Middle Congo to become French Equatorial Africa. In 1946, the French granted internal self-government. On August 13, 1960, President David Dacko proclaimed complete independence but alarmed the Western powers when he aligned with communist CHINA. He was overthrown in a coup on December 31, 1965, by Jean-Bédél Bokassa, his cousin and army chief of staff, who then declared himself Emperor Bokassa I.

Allegations of brutality and excess characterized his regime, with Amnesty International charging he participated in the massacre of 80 schoolchildren. In 1979, he was ousted by a coup supported by French paratroopers. Dacko returned to power, but an army coup deposed him again. From 1996 to 1998, violence between the government and rebel groups prompted the United Nations to send in an all-African peacekeeping force. Although elections were held in September 1999, repeated coups have followed.

Although the nation is rich in natural resources, including diamonds, gold, and oil, more than 70 percent of its citizens are subsistence farmers working only 3 percent of the land. Large stands of timber cover 75 percent of the country and surveys suggest extensive

additional mineral wealth. Poaching has diminished the republic's reputation as one of the last great wildlife refuges and the populace suffers from a high mortality from AIDS, with 13 percent of the population HIV positive. Life expectancy is 41.71 years.

The official language is French, but Sangho is used for commerce and intertribal communication between 80 ethnic groups, of which the largest are Baya (34 percent), Banda (25 percent), Nabandi (11 percent), Azande (10 percent), and Mbaka (5 percent). In July 1990, a decree gave the nation's 10,000 pygmies full citizenship. A small European community remains, the majority of which are French or Portuguese descendants. Christians account for 83 percent of the population, of which 33 percent are Roman Catholic and 50 percent are Protestant. An estimated 12 percent of the population follows animist traditions and 3 percent are Islamic.

## Central America Free Trade Agreement

THE CENTRAL America Free Trade Agreement (CAFTA) is a treaty between the UNITED STATES and the countries of Central America (HONDURAS, GUATEMALA, EL SALVADOR, NICARAGUA and COSTA RICA)—what the Russians refer to as the "near abroad." This is a parallel to the earlier NAFTA (North American Free Trade Agreement). The objective is a free-trade association between the countries of Central America and the United States. It is to replace the Caribbean Basin Initiative (CBI), a unilateral agreement by the United States allowing 80 percent of Central American products to enter the United States with minimal or no duty. The CBI was designed to expire in 2007. This new agreement will focus on the land-based countries and not the islands.

As with NAFTA, the objective of the agreement is to create a common set of rules and standards to regulate commercial trade in both goods and services. It

also has the objective of creating an economic environment that will benefit local people and thus create more stable governments. To this end, governments must privatize current government monopolies. Government-owned telecommunications were a major sticking point for Costa Rica, which at the end of 2003 asked for more time to negotiate and adjust. As of October 2003 all countries, except Costa Rica, had reached agreement. Costa Rica sought and was given an extended period for final negotiations.

The United States is the main customer of Central America (\$11 billion in 2002—over 43 percent of total exports from Central America). Conversely, the U.S. trade with Central America is more than its trade with INDIA and RUSSIA combined. With the implementation of CAFTA (with or without Costa Rica) this trade is likely to increase rapidly. In addition, there will be many more American companies willing to open new businesses in Central America.

A hidden wild card in all this is the future status of CUBA. It is widely agreed that once the U.S. embargo on Cuba ends, Cuba will become the dominant economic power in the Caribbean Basin. NAFTA and CAFTA may provide sufficient regional cooperation to also provide competitive strength when this happens. It seems that the strategy of CAFTA is to provide a treaty distinct from anything that may occur in the islands.

## central business district

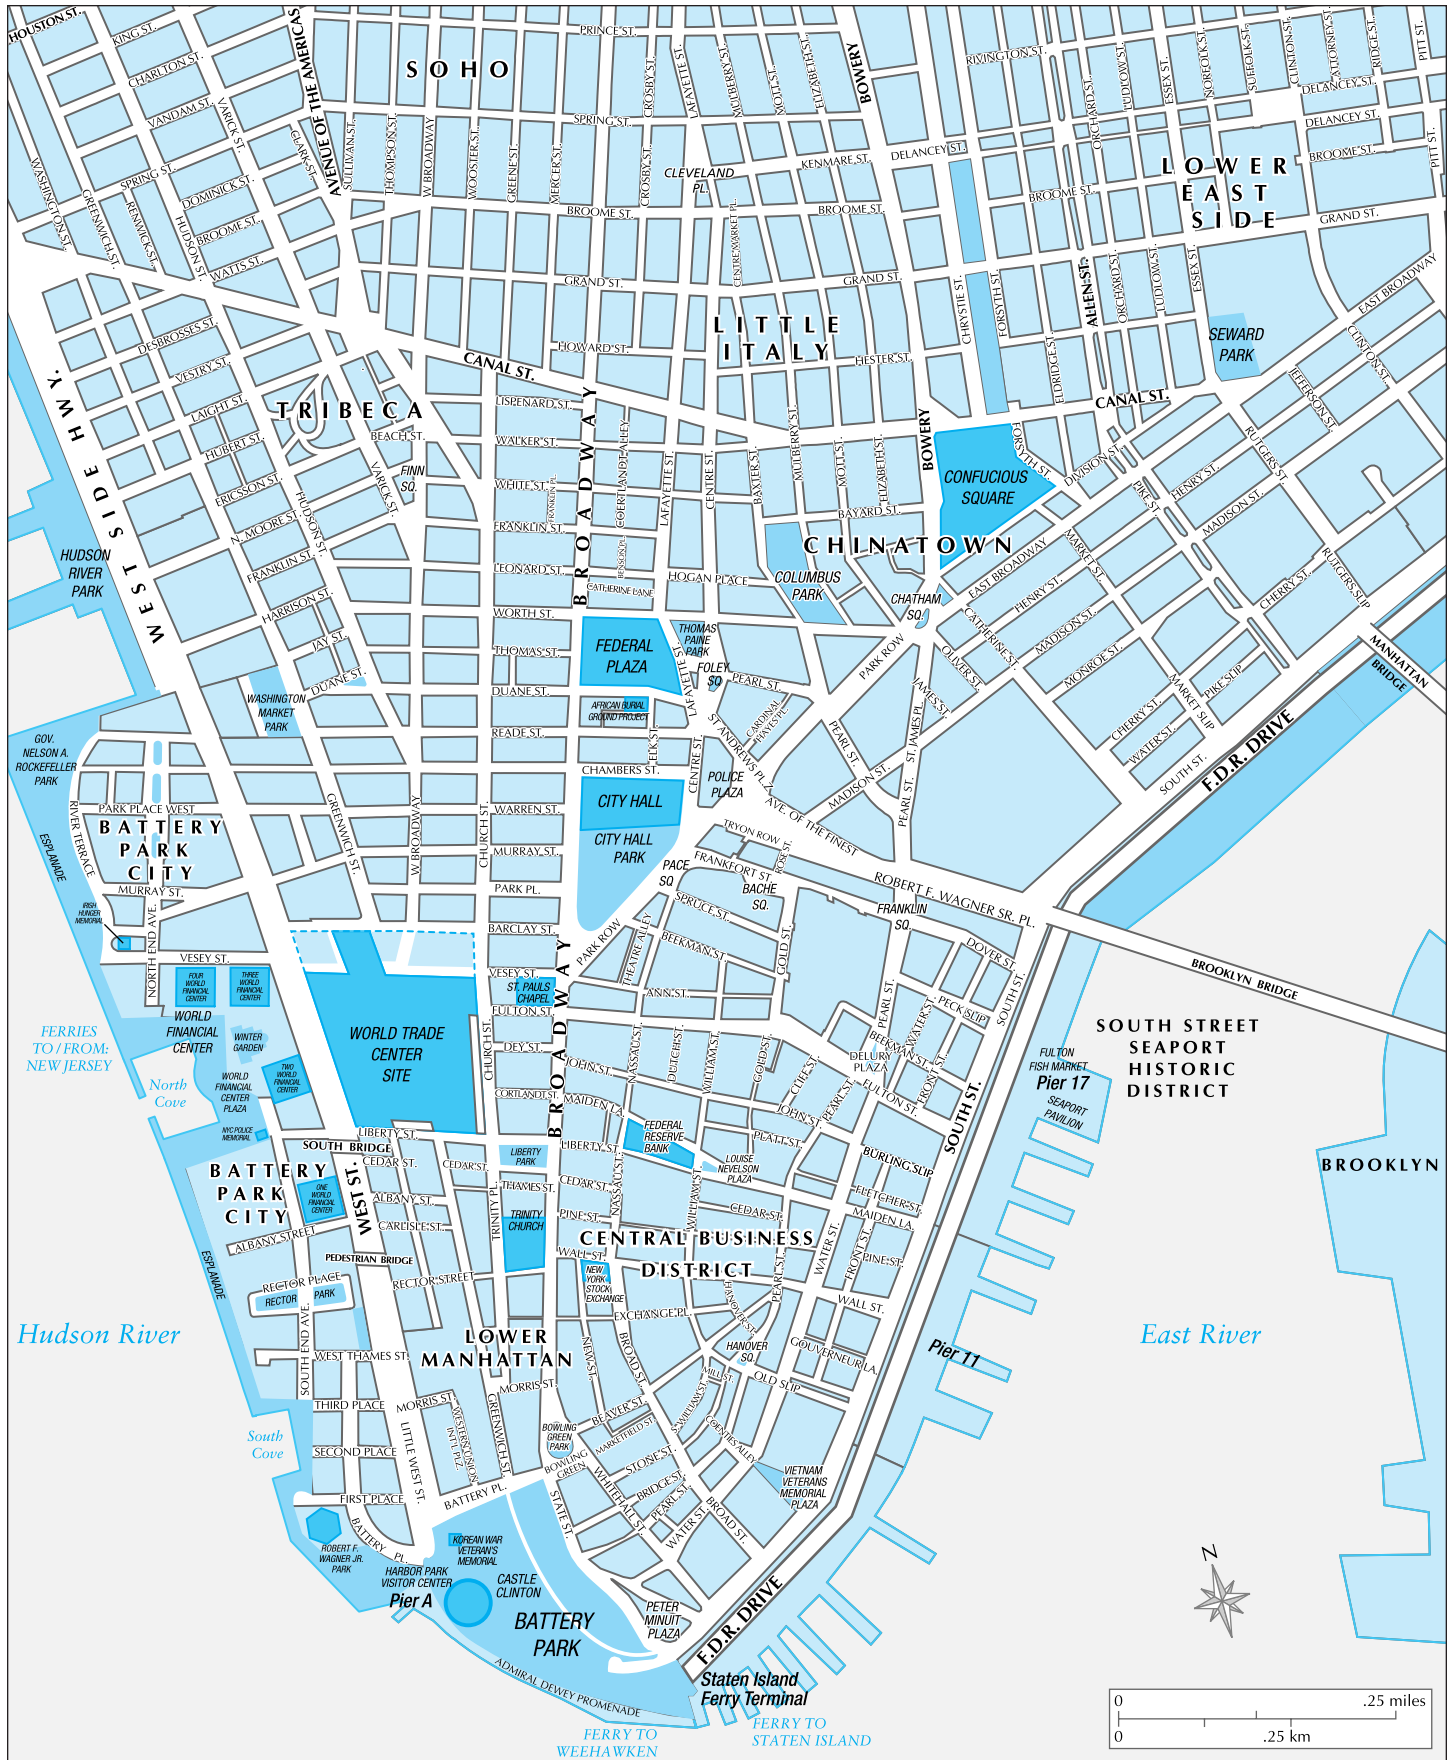

A CENTRAL BUSINESS District (CBD) is the nucleus or downtown of an urban area that contains the main concentration of commercial land use, with the highest percentage of retail shops, offices, and services such as banking and finance. Large cities are characterized by distinct retail sub-areas that have their own “walking district.” Some specialized clusters of nonretail activities can be found, such as law offices, medical facilities, and offices services. Applicable to any city, the CBD is

found in global cities with international and financial business centers such as NEW YORK, LONDON, TOKYO, PARIS, Frankfurt, Zurich, Amsterdam, LOS ANGELES, HONG KONG, and SINGAPORE. In global cities where the CBD is strong, advantages include local expertise, world-class technology, specialized knowledge, and networking capabilities. There are slight differences in the patterns of CBDs around the world.

The concentration within a CBD is associated with high land values because of high accessibility. These characteristics of urban location are similar to the William Alonso model. The CBD has been identified as a district area after the general theories of city structure in the 20th century. There has been no specific defined geographic area for a downtown, unlike the boundaries of a city for example. In their pioneer work, the urban geographers, Raymond Murphy and James Vance (1954), found a number of indices by which the CBD could be physically delimited. However, their method required a large amount of land use and building use data, and thus it was rarely used. The CBD has the highest concentration of land uses and in general the tallest nonresidential buildings. It is spatially structured internally, with different specialist areas to benefit from the external economies associated with agglomeration. Vertical segregation exists also with uses that can afford the highest rent on the ground floors of high-rise buildings.

Methods for the delimitation of the CBD include mapping land use intensities referring to the central business height index, recording the percentage of the land uses of each floor of each building within the CBD, and calculation of high-level pedestrian flows. The Manhattan CBD is, for example, characterized by very high offices blocks and a lack of residential buildings, which has the result making the area deserted after offices hours. In the 1970s, planners introduced the development of a resident-friendly concept, such as gentrification, to bring night life back to the downtown area. The Marunouchi District, the heart of Tokyo's CBD located near the Tokyo Station (through which more than 700,000 passengers each day commute), is characterized by the new massive Marunouchi building complex. It attracted more than 13 million visitors during its first six months.

However, characteristic of many CBDs, the three Tokyo core wards of Chiyoda, Chuo, and Minato have a nighttime population of 268,000 persons but a daytime population is 2.341 million persons. Some large cities as London and Tokyo have several CBDs. Moreover, if the CBD remains a strategic area for leading

industries, it is reconfigured by technological and economic change. Many CBDs are facing several problems, such as congestion that has led to parking restrictions, and decline not only with the increasing growth of out-of-town developments with shopping centers and office parks very close to major highway intersections, but also with the cyclical decrease of business activity.

In New Orleans, LOUISIANA, after the oil industry collapse in the 1980s, almost all office inventory was abandoned as companies went out of business; and the occupancy of the CBD only ever achieved 90 percent of the capacity. After the technology bubble burst in San Francisco, CALIFORNIA, office space rates fell as much by half.

### NEW BEIJING CBD

In booming economies such as in CHINA, infrastructures in new CBDs are being built. In BEIJING, workers are clearing the CBD of its aging textile factories and railroad workshops for a \$20 billion complex. This new CBD is a way for China to create an image of a modern capital in line with London, Paris, and New York. The conventional CBD, as a highly concentrated core with international business, has been questioned in light of the information technology age. If centrality was synonymous with the CBD, today the new technologies and the organizational forms have changed the spatial correlates of centrality. Some questions on the future of financial districts have been raised, particularly when looking at the virtual configuration of the electronic system.

The informational economy tends to be concentrated in global cities, creating a new international division of labor. Global cities come at the top of the information hierarchy and are characterized by a high concentration of information flow and processing. The accessibility and centrality for a CBD is no longer justified, as was the case when face-to-face contacts were a necessity in business. However, clustering of services and proximity do produce agglomeration economies, and in a CBD, the services and marketing relations can, for example, enhance the quality of the services.

WASEDA UNIVERSITY, JAPAN

## Chad

**Map Page** 1115 **Area** 495,752 square mi (1,284,000 square km) **Population** 9,253,493 (2003) **Capital** N'Djamena **Highest Point** 11,204 ft (3,415 m) **Lowest Point** 525 ft (160 m) **GDP per capita** \$1,000 **Primary Natural Resources** petroleum, uranium, fish.

THE REPUBLIC OF CHAD is a LANDLOCKED country located in north-central Africa. It is bounded by LIBYA, NIGER, NIGERIA, CAMEROON, the CENTRAL AFRICAN REPUBLIC, and SUDAN. The country is about 85 percent of the size of ALASKA. Chad got its name from Lake CHAD, which lies on the western border with Niger and Nigeria. The lake decreases in size during the dry season. The south is mostly wooded terrain, which becomes brushy as you near Lake Chad. From the lake, the land rises gradually to the Ennedi Plateau and the Tibesti Ranges, formed from volcanoes. Some of the mountains reach a height of 11,000 ft (3,353 m). The SAHARA DESERT covers part of the northern half of the country. The two important rivers in Chad, the Chari and the Logone, both flow into Lake Chad. They are used for crop IRRIGATION and during some seasons are navigable.

There are three climatic regions in Chad. The south has a more tropical climate, with wet and dry seasons. The central zone is covered by sand and has light rain. The northern area has a true desert climate, with hot, arid conditions and almost no rain. Chad's population is made up of many different ethnic groups. Most of the population is concentrated in the south, and the people there live sedentary lives, pursuing agriculture. The people include the Sara, Massa, Ngambaye, and Moundang. Most of them are Christians, but a few still follow traditional religions.

The people of the north are nomadic or seminomadic and are Muslims. They include Arabs, Tuareg, Hadjerai, Fulbe, and Toubou. There are two official

languages in Chad—Arabic and French. Many of the people speak tribal languages and dialects, too.

N'Djamena, the capital and largest city, has about 530,000 people. Other cities include Moundou, Sarh, and Abeche.

The southern area, around Lake Chad and the two rivers, is the most fertile area of Chad, and most of the food for the country is grown there. It is also the only area with much animal life, which consists mainly of birds and antelope. Economic development in Chad has been severely hampered by its landlocked position, poor transportation, political turmoil, and lack of natural resources. Some textiles are produced in Chad, and there are food-processing operations as well. Their imports of machinery, transportation equipment, food, petroleum products and industrial goods outweigh their exports of cotton, cattle, textiles, and fish. Their chief trading partners are SOUTH AFRICA, Cameroon, and FRANCE. Chad has one of the lowest per capita incomes in the world.

Chad's position near Lake Chad has always made it a focal point of Saharan trade routes. This has caused dissension and turmoil through the years, as different groups wanted to control the routes. Finally, a democracy was established in 1996 and multiparty presidential elections were held. But since that time, there have been disputes and fighting within the country.

## Chad, Lake

**LAKE CHAD** IS A shallow freshwater lake located in west-central Africa. Only 23 ft (7 m) at its deepest, it is 820 ft (250 m) above sea level, and was once larger than the state of VERMONT. In the 1960s, Lake Chad was approximately the size of lake ERIE, one of the Great Lakes located in the Midwest region of the UNITED STATES. In the past 40 years, however, Lake Chad has shrunk to less than the size of RHODE ISLAND. Reasons are twofold: a drier climate, with less water replenishment by monsoons; and water siphoned off for agricultural irrigation purposes has quadrupled to provide for the 20 million people living in the four

countries (Chad primarily, but also CAMEROON, NIGER, and NIGERIA) that include Lake Chad in their borders.

To illustrate the lake's reduction: Its surface area measured 10,000 square mi (25,000 square km) in 1963 but had shrunk to 839 square mi (1,350 square km) by 2001, causing the lake to become one-twentieth of its original size. The most significant decrease occurred between 1973 and 1987. Still, Lake Chad is the fourth-largest lake in Africa, with only Lakes VICTORIA, TANGANIKA, and MALAWI superior in size. It is a central point of the region for many reasons, including the important archaeological discoveries found nearby. This region contains some of the earliest evidence of hominids; the area has been occupied, nonstop, since perhaps 500 B.C.E.

Other pivotal roles of the lake and its perimeter include the area's prominence in the region's trade, the massive irrigation projects that rely upon its waters, and the flora and fauna that grow—and the wildlife that live—nearby. Fish quantities, however, are significantly decreasing, a concern since fish provide a source of protein for the population.

Because of the decrease in fish, along with other signals of environmental distress, the lake and surrounding basins have been declared a "disaster zone." A research paper exploring the devastation, "Human and Natural Impacts on the Water Resources of the Lake Chad Basin," appeared in the American Geophysical Union's *Journal of Geophysical Research* in 2001. Britain's Department for International Development in Nigeria, however, offers a more optimistic outlook. According to their experts, the shrinkage of Lake Chad has created more farmland, land that is fed by the lake when its boundaries expand during rainy weather. Leftover fish manure fertilizes this farmland, adding to fertility, and this combination allows farmers to survive three-month drier periods. Significant famines have not occurred in this region, and people living by the lake are effectively fed by agriculture.

## Changjiang (Yangzi River)

THE CHANGJIANG cuts through the heart of CHINA and is regarded by the Chinese as the geographical marker dividing the country into north and south. It winds its way through the 10 provinces of Qinghai, Tibet, Yunnan, Sichuan, Hubei, Hunan, Jiangxi, Anhui, Jiangsu and Shanghai before reaching the East China Sea. Its fertile ALLUVIAL PLAINS produce great amounts of wheat, cotton, tobacco and silk. The Changjiang or Yangzi River dominates the center of China both north-south and east-west. It is thus one of the major factors affecting China's future industrialization and food production.

Changjiang means "long river" and that it is. China's Changjiang is the third-longest river in the world (after the AMAZON and NILE). It is over 3,960 mi (6,300 km) long and comparable in economic importance to the MISSISSIPPI in the UNITED STATES. Originating in the Tanggula Shan of eastern Tibet, the Changjiang passes through and links the fertile Red Basin of Sichuan province with the THREE GORGES and their new and massive hydroelectric project as well as the central food basket provinces of Hunan-Hubei. It finally exits to the sea at Shanghai. Altogether it links eight provinces, several major urban and industrial cities and innumerable ecological regions.

The Changjiang is China's longest navigable river; ocean-going ships are still able to pass as far inland as the Municipality (an autonomous city) of Chongqing. It also is China's major hydroelectric focus. The Three Gorges Project is designed to provide clean electric power to all of Sichuan and as far eastward as the Shanghai economic cluster. Just from Sichuan to Shanghai, the Changjiang corridor produces 40 percent of the nation's grain, including 70 percent of the rice, 33 percent of the cotton, 48 percent of the freshwater fish, and over 40 percent of the total industrial output, which is likely to increase significantly with completion of the Three Gorges project. And with an abundance of fresh water, there are plans to divert some to water-deficit areas in North China.

The key to understanding the geography, and thus the human significance, of the Changjiang is to realize that it is one river that links six distinct geographic environments and cultures. (Think of these as like a series of distinct boxcars along a rail line with the river being the connector or "line." Each "car" contains distinct cities, climates, and economics.)

*Chamdo-Tibet:* This beginning of the Changjiang is an area of steep valleys, heavy snowfall, and strong

springtime floods. None of the river is navigable, soils are rocky and slopes steep, thus preventing any large-scale settlement by farmers. Most people are Tibetan or tribal and not of the dominant Han Chinese.

*Sichuan:* Leaving the TIBETAN PLATEAU the river's tributaries add water to form that portion in the Red Basin which was the site of the ancient Shu culture. Once a large lake, and with a mild climate, the Sichuan or Red Basin has very fertile soils. This has meant a surplus of food and a very large agrarian population. Until it reaches the area near modern Chongqing, it is navigable to only moderate-sized boats still capable of carrying significant cargoes.

*Three Gorges:* The site of the ancient Ba culture, the mountains that separate the Red Basin from the Central Plains of eastern China force the Changjiang into a narrow channel that contains a series of small inner basins with a mild climate but limited level land for agriculture. Most life focuses on the river, transportation, and light industry.

There are three distinct gorges to pass through before the river debouches into the area known as eastern China. It is the final downstream gorge that has become the site for the controversial Three Gorges Dam. The area is designated ultimately to form a separate province (Sanxia or "Three Gorges").

*Liang Hu* (Two lakes, Poyang and Dongting): Once past the Three Gorges, the Changjiang enters what has been called "China's rice bowl," so named because of its abundant production. Stretching more than 630 mi (1,000 km), it is an area of many small and two large lakes, and because three other rivers enter the river here, it is prone to flooding. Historically, the basis for natural flood control was the fact that the two large lakes (Dongting and Poyang) could absorb the floodwaters. For example, Poyang Lake rises 36 ft (11 m) during the wet season. Dongting Lake expands to more than three times its dry season size and is more than 33 ft (10 m) deeper during the summer rains. This area supports immense agrarian and industrial populations and is a major east-west as well as north-south junction for transportation in all eastern China.

*Dabie Mountains:* The last CHOKE POINT for the Changjiang before it makes a final surge to the sea is created by the Dabie Mountains. The area is unsuitable for damming, but it still creates a constriction that often holds the river's high waters in the central basins, causing flooding. Were it not for the large lakes of Hunan and Jiangxi provinces, which can absorb much of these high waters, the entire area would have remained a lake or swampy area.

*Nanjing to Shanghai:* Between the one-time southern (*nan*) capital (*jing*) and Shanghai, the Changjiang has its greatest volume and flow. This section is wide and deep and has long been a kind of inland shipbuilding and port area. The area south of the river is largely mountainous and forest covered (thus providing timbers for boat building) and has a mild subtropical climate ideal for tea and citrus fruits, all of these being longtime specialties.

Today, Shanghai, at the mouth of this great river and despite its swampy physical geography, is China's largest and most modern city. It soon will replace HONG KONG as China's most international city, and the Changjiang will become one of the world's most important industrial arteries.

## Chechnya

CHECHNYA IS A constituent republic of the Russian Federation, situated on the northern slopes of the CAUCASUS MOUNTAINS. Since the early 1990s it has been partially controlled by rebel groups who have attempted to proclaim a separate Chechen republic. The conflict between the Russian government and Chechen separatists has now lasted over a decade and has claimed an estimated 150,000 lives. Although the surface issue of the conflict is nationalist and religious identity, a more serious issue lies beneath and ensures that the conflict will continue: the presence of oil and the location of Chechnya in the middle of one of the region's major pipelines.

The Chechen Republic occupies the middle portion of the Terek River Valley, which rises in the Caucasus Mountains and flows east into the CASPIAN SEA. The southern portion of the country rises sharply to the Front Range of the Caucasus, culminating at the area's

tallest peak, Tebulosmta (14,734 ft or 4,492 m), while the northern part of the country descends to the dry lowlands of the Nogay Steppe. Chechnya's capital and main city is Grozny, located on the Sunzha River, in a narrow valley between two ridges that run parallel to the Caucasus. Much of the city is in ruins. Many of Chechnya's oil fields are located right in Grozny, or close by. The city also has a number of mineral springs. The other major river in Chechnya is the Argun, which flows down from the Caucasus heights and joins the Terek near the city of Gudermes, another major oil-field. Major pipelines run across the northern part of the country, following the Terek Valley.

The Chechens were formerly linked with their neighbors to the west in the Chechen-Ingush A.S.S.R. Today, a separate Ingush republic borders Chechnya to the west, along with the autonomous republic of North Ossetia, the Russian *krai* (district) of Stavropol to the north, and the autonomous republic of Dagestan to the east. To the south, Chechnya shares a remote border with GEORGIA, high in the Caucasus Mountains. The republic covers about 6,747 square mi (17,300 square km) and contains roughly 1 million people, the largest ethnic group in the North Caucasus. They call themselves Nokhchi and share linguistic traits with other Caucasian peoples.

Most Chechens are Muslims, and much of their history is affected by their relationship with other Islamic peoples in the region. Traditional Chechen society was clan-based, similar to highland peoples in other parts of the world, but a common identity was forged through some of the longest colonial struggles in world history, defying incorporation into the Russian Empire for nearly a century. Fierce resistance continued after formal annexation in 1859, inspiring romantic visions of heroic mountain rebels in Russian literature and art.

The Soviets, too, had their struggles with the Chechens, culminating in the forced deportation of nearly the entire nation to Central Asia and Siberia after World War II. The Chechens were allowed to return home under the Khrushchev administration, which also attempted to bring technological and industrial advances to the region for the first time. The Chechen capital of Grozny soon became one of the centers of the Soviet oil industry. By the 1990s, it is estimated that Chechnya produced 4.2 million barrels of oil a year, and refined another 18 million, contributing up to 6 percent of the gross domestic product for the entire Soviet Union.

A major pipeline was built to transport oil from Baku and the Caspian Sea to Novorossiysk and other

ports on the BLACK SEA for export. Since 1994, this business has almost entirely collapsed.

Chechnya is linked politically, economically, and culturally to RUSSIA. And although much of the country is under the control of either the self-proclaimed Chechen Republic of Ichkeria (recognized by no other nation), or independent regional warlords, it is estimated by both pro- and anti-Russian news sources that most Chechens support autonomy but not independence from the Russian Federation.

Since 1999, fighting has broken out again, this time in connection with pan-Islamicist movements in Dagestan, and possibly with global terrorist organizations, though the extent of this connection is speculative. Much of the shattered economy is run by organized criminal gangs, and a large part of educated Chechen society has left for Russian cities.

A referendum sponsored by Moscow in March 2003 approved a new constitution granting autonomy but it stipulated firmly that Chechnya remain a part of Russia. Tensions were not calmed by this move, and they escalated further with the assassination in May 2004 of the Moscow-backed Chechen president, Akhmat Kadyrov. The former president, Aslan Maskhadov, barred from the elections of 2003, now heads the separatist movement and has stated that he has enough men, arms, and resources to continue the fight against Russia for many years to come.

## Chile

**Map Page** 1141 **Area** 302,778 square mi (756,950 square km) **Population** 15.2 million **Capital** Santiago **Highest Point** 22,573 ft (6,880 m) **Lowest Point** 0 m **GDP per capita** \$4,200 **Primary Natural Resources** copper, fish, agricultural products.

CHILE IS A LONG and narrow country in South America, about 3,999 mi (6,435 km) long and an average of 112 mi (180 km) wide. From west to east, the country is divided in three distinctive geographical spaces: the Pacific coast, the intermediate depression (*depresión intermedia*), and the ANDES.

A mountain range known as the Cordillera de la Costa (Mountains on the Coast) separates the coast from the intermediate depression. The ocean has abundant natural resources, the southern intermediate depression has rich soils, and the Andes has provided essential hydraulic (rivers that flow from east to west) and mining resources, and has had a crucial effect on the climate. In addition to its South American territory, Chile has rights to parts of the Antarctic continent and island territories off its coast in the PACIFIC OCEAN (most notably EASTER ISLAND).

### NORTH TO SOUTH

From the far north to the extreme south, Chile has a large variety of climates, environments, natural resources, and vegetation. The Great North (Norte Grande), what today includes the regions of Tarapacá and Antofagasta, was incorporated to the country following the War of the Pacific (1879–83) against BOLIVIA and PERU. This region includes the Atacama Desert, one of the driest deserts in the world, and with the exception of a few oases, the environment is extremely harsh, water resources are limited, and vegetation is scarce. The principal cities are located along the coast, where there is also an important and growing fishing industry. The interior and the northern Andes are rich in mineral resources. Nitrate was exploited between 1880 and 1930s. In the 1930s, large-scale copper replaced nitrate as the most important Chilean export. Today, the mine of Chuquibambilla continues to be the largest open-pit mine in the world.

South of the Great North lies the regions of Atacama and La Serena. The environment is less extreme, and the presence of rivers and valleys facilitates the development of small-scale agriculture. These regions have also been important for small-scale mining. To the east, the skies are particularly clear, attracting astronomers and space scientists from all around the world.

Despite the efforts of decentralization, the center of Chilean political, social, and industrial life continues to be the Central Valley. About 70 percent of the population lives in the Central Valley (which includes the regions of Valparaíso, O'Higgins, and Maule and the

A third of the population of Chile lives in the capital city, Santiago, where environmental problems affect the populace.

Metropolitan or capital region). As with many other Latin American capitals, Santiago suffers acute problems of atmospheric pollution and congestion. The central valley has a Mediterranean CLIMATE and rich soils, favoring the development of agriculture. Today, fruit and wine have become important commodities.

Abundant rainfall and vegetation characterize the southern provinces. Fishing, agriculture, and livestock have been among the most important economic activities. The city of Concepción, the third-largest city in the country, has substantial industrial activity, making a pole of development and growth in the south. South of Concepción and the the Bío Bío River lies La Frontera, which until the 1870s under the control of the Mapuches, native Latin Americans who had successfully resisted Spanish colonization. Today, the Mapuches are still struggling to recover their land and be recognized as a distinctive ethnic group in the country. Further south lies the lake region. Settled by German immigrants in the mid-19th century, its amazing beauty, lakes, and volcanoes have made it a favorite tourist destination.

While a third of the national territory lies south of the city of Puerto Montt and the Seno de Reloncaví, it has only about 3 percent of the country's population. Poor transportation has made communication difficult.

Only in 1988, the country inaugurated the Southern Highway, a 683-mi (1,100-km) road that joined Puerto Montt and Puerto Yungay. Historically, the city of Punta Arenas has been an important port strategically located in the Strait of Magellan. Today, the region of Magellan is also important because of the petroleum industry.

## China

**Map Page** 1120 **Area** 3,645,468 square mi (9,596,960 square km) **Population** 1,298,847,624 **Capital** Beijing **Highest Point** 29,035 ft (8,850 m) **Lowest Point** -505 ft (-154 m) **GDP per capita** \$5,000 **Primary Natural Resources** coal, iron ore, petroleum, natural gas.

CHINA IS ONE of the largest countries in the world, with more than 3.6 million square mi (9.6 million square km) of land stretching from the PACIFIC OCEAN in the east to the towering glacial summits of the HIMALAYAS and Karakorum mountains in the west. From north to south, this Asian giant covers more than 30 degrees of latitude, extending from the edge of Siberia southward into the tropics near VIETNAM. Traveling from east to west, the land rises in a series of steps from the coastal zone of the North China Plain to the top of the world on the TIBETAN PLATEAU.

The country's terrain is diverse, with vast deserts, stands of forest, numerous mountain ranges, major river basins, high plateaus, extensive GRASSLANDS, and rich plains. On and below the surface, the land has extensive reserves of natural resources that provide the nation with enormous potential wealth. China ranks first in the world in population (1.3 billion), equal to 22 percent of the world's total. The population is as varied as the landscape. The Han are the most numer-

ous of the 56 recognized nationalities, accounting for 92 percent of all Chinese. China has borders with North KOREA to the east; MONGOLIA to the north; RUSSIA to the northeast; KAZAKHSTAN, KYRGYZSTAN, and TAJIKISTAN to the northwest; AFGHANISTAN, PAKISTAN, INDIA, NEPAL, Sikkim and BHUTAN to the west and southwest; and Vietnam, LAOS and MYANMAR to the south. Across the seas to the east and southeast are South KOREA, JAPAN, the PHILIPPINES, BRUNEI, MALAYSIA, and INDONESIA.

Politically, the country is organized as a republic and divided into 21 provinces, 5 autonomous regions, and 4 special municipal districts. The president serves as the head of state, the Communist Party, and the army, with a prime minister supporting as the head of government. In addition to the president and prime minister, leadership is managed through the People's Congress, which provides popular representation, and a Communist Party Standing Committee, which provides direction and leadership.

China now has 668 cities, of which 13 have populations of more than 2 million and 24 between 1 and 2 million. SHANGHAI is the largest city by urban population with 14.7 million at the end of 2003. The other major cities are BEIJING, Tianjin, Chongqing, Xi'an, Wuhan, Guangzhou, HONG KONG, Chengdu, Shenyang, and Shenzhen.

## GEOGRAPHY

China's topography started forming millions of years ago as the Indian landmass (plate) pushed northward into Eurasia, raising the landscape higher and higher and forming the Qinghai-TIBETAN PLATEAU. Often called the roof of the world, this plateau averages more than 9,840 ft (3,000 m) above sea level and includes most of the world's highest mountains. As a result, China's terrain descends in a series of steps from west to east.

The second step includes the gently sloping Inner Mongolia Plateau, the Loess Plateau, the Yunnan-Guizhou Plateau, the TARIM BASIN, the Junggar Basin and the Sichuan Basin, with an average elevation of between 3,000 and 6,000 ft (1,000 and 2,000 m). The third step, dropping to 1,500 to 3,000 ft (500 to 1,000 m) in elevation, extends eastward from the Greater Hinggan, Taihang, Wushan, and Xuefeng mountain ranges to the coast of the Pacific Ocean. Throughout this zone are China's major agricultural plains, the Northeast Plain, the North China Plain, and the Middle-Lower Changjiang Plain.

Mountains represent a major feature of China's physical geography, with mountains and associated

plateaus and hills accounting for about 65 percent of the country's landmass. Within this mountainous setting are 90 percent of China's forests, 77 percent of its pastures, 76 percent of its lakes, and 98 percent of its hydropower resources.

With a mountainous topography, distinct vertical zonation, and a monsoon-oriented weather regimen, it is no wonder that China has over 1,500 rivers. Most of the major rivers have their source on the Qinghai-Tibet Plateau and drop rather dramatically during the first third of their course. China's many rivers can be categorized as exterior and interior systems. The catchment (drainage) area for the exterior rivers accounts for 64 percent of the country's total land area.

The Yarlung Zangbo River in Tibet, which ultimately empties into the INDIAN OCEAN, boasts the largest canyon in the world, the Yarlung Zangbo Grand Canyon at 131 mi (504 km) long and 19,700 ft (6,009 m) deep. The catchment area for the interior rivers that flow into inland lakes or disappear into deserts or salt marshes makes up about 36 percent of China's total land area. China's longest inland river, the Tarim (1,300 mi or 2,179 km), flows from west to east across the northern edge of China's greatest desert, the Taklamakan, before disappearing into the sands near Lop Nor, a large inland lake that looks a lot like a human ear if you see it from space.

With headwaters high in the Tibetan Plateau, the CHANGJIANG (Yangzi) at 3,900 mi (6,300 km) is the longest river in China and in all of Asia. It is also the third-longest river in the world, next only to the NILE in Africa and the AMAZON in South America in length. With a catchment basin of more than 700,000 square mi (1.8 million square km), its BASIN is more than twice as large as that of the HUANG (Yellow River). Also known as the "golden waterway" in its upper reaches, the Changjiang serves as an important trade and transportation route from Sichuan Province to the sea.

The second longest river in China is the HUANG (Yellow) River with a length of 5,464 km (3394 mi). The Yellow River valley was one of the birthplaces of ancient Chinese civilization. It has lush pasturelands along its banks, flourishing agriculture and abundant mineral deposits. The Heilongjiang is the largest river in north China, of which 1,925 mi (3,101 km) are in China. The Pearl River (Zhujiang), 1,376 mi or 2,214 km long, is a major river in south China. In addition, China has the most famous man-made river in the world—the GRAND CANAL, which runs from Hangzhou in Zhejiang Province in the south to Beijing in the north. Work on the Grand Canal began as early as the

*For centuries, the Great Wall has served as a barrier between Inner China and the less hospitable Outer China.*

5th century, but many of its most important extensions (to Beijing) occurred under the Mongols of the Yuan Dynasty. The canal links five major rivers: the Haihe, Huang, Huaihe, Changjiang and Qiantang, and with a total length of 1,100 mi (1,801 km), is the longest and oldest man-made waterway in the world.

China has 507,000 square mi (1.3 million square km) of cultivated lands (about 9 percent of the world's total), distributed primarily in the Northeast Plain, the North China Plain, the Middle-Lower Changjiang Plain, the Pearl River Delta, and the Sichuan Basin. The fertile soils of the Northeast Plain, the largest plain in China, have a dark black color and used to produce

wheat, corn, sorghum, soybeans, flax, and sugar beets. The brown soils of the North China Plain just to the south are planted with wheat, corn, millet, and cotton.

The terrain of the Middle-Lower Changjiang Plain is noticeably flat and particularly suited to paddy rice. Because the area's abundant lakes and rivers are used extensively in freshwater fish farming, this part of China has the distinction of being called the "land of fish and rice." The area also produces large quantities of tea and silkworms, both key factors throughout China's long economic history.

The soils in the Sichuan Basin, an ancient dried-up lakebed in the upper Changjiang Basin, have a reddish tint that has given rise to the basin's other name, the Red Basin. Because the climate of the basin is warm and humid, this "land of plenty" is green with crops in all four seasons, including paddy rice, rapeseed, and sugarcane. The Pearl River Delta along the southeast coast near Hong Kong abounds with paddy rice, gathered two to three times every year.

Forests cover approximately 621,000 square mi (1.6 million square km) of China, spread throughout the mountain ranges of the northeast and in southwest China, particularly Yunnan Province. Because Yunnan is crossed by the TROPIC OF CANCER along its southern edge, it is often called the "kingdom of plants," especially at Xishuangbanna in the very southwest corner, where a rare tropical broadleaf forest plays host to more than 5,000 plant species.

Grasslands in China cover an area of 1.6 million square mi (4 million square km), stretching from the northeast to the southwest. They are the centers of animal husbandry. The Inner Mongolian Prairie is China's largest natural pastureland, and home to the famous Sanhe horses, Sanhe cattle, and Mongolian sheep. The important natural pasturelands north and south of the TIAN SHAN MOUNTAINS in XINJIANG are ideal for stock-breeding.

China is rich in mineral resources, and all of the world's known minerals can be found here. To date, geologists have confirmed reserves of 158 different minerals. These include 10 energy-related minerals, including oil, natural gas, coal, and uranium; 54 metallic minerals, including iron, manganese, copper, aluminum, lead and zinc; and 91 nonmetallic minerals.

## REGIONS

One of the easiest distinctions to make is that between Outer China and Inner China. Surrounding China on the north and west is a series of lands that have for centuries been "beyond" the Wall (Great Wall). Lands

where water and rainfall are scarce and animal husbandry takes precedence over crops. Lands where the soils are rocky and sandy, where altitude keeps the earth frozen for much of the year, and where treeless plains stretch beyond the imagination. It is also a land that drains to the interior of the continent and not to the sea.

These lands beyond the Wall are extremely remote and generally inhospitable. Where human habitation has taken hold, in those areas where the soils are more protected and water is sufficient for some form of agriculture, the peoples tend to be non-Chinese with traditions and connections to history and geography far removed from those of China's core peoples. Because this landscape provides so little (if anything at all) in the way of natural support for the traveler or an invader, it has always served as a natural buffer between China proper and the outside world and a way for the Chinese to choose where and when they meet the outside world. For this reason, the area has typically been poorly connected with the rest of the country, a historical design that has proven to be a major obstacle to development as China begins the 21st century.

## OUTER CHINA

Outer China consists of much more than just Tibet, the first area that most foreigners recognize or think of as being outside of China proper. The area also includes the Inner Mongolian and Xinjiang Autonomous Regions, plus Qinghai Province. Gansu Province and the Ningxia Autonomous Region could also be included. It is a vast area, covering some 2 million square mi (5 million square km), slightly more than 53 percent of the country's total land area. That means that if you just considered Outer China alone, it would be the seventh-largest country in the world, an area 10 times that of FRANCE.

Within this landscape are some 50 million people, a number that is large by any standard other than China, where it represents only 4 percent of the population. This empty landscape is empty for a reason; The land just cannot support large numbers of people. And where it can support life, it does so best with grazing animals and animal husbandry.

Inner Mongolia (23 million people) and Xinjiang (19 million people) are clearly the most prosperous of the region's four-plus administrative divisions, with most of the limited arable land. But the prosperity associated with these pockets of development is far from uniform. In spite of the fact that we have chosen to group these lands together under one heading, they are

so distinctive individually that it is valuable to give each a little extra attention before moving on.

The Inner Mongolian Autonomous Region (one of five such regions in China) is part of the great Mongolian Steppe (lands of Genghis Khan and the Mongol horde), a plateau region that averages about 3,280 ft (1000 m) above sea level and extends from China's border with Russia in the northeast to the deserts of Xinjiang in the northwest. Most of the land is covered to some degree by grass, although there are areas of woodland and forest in the extreme northeast, an incredible wetland region (Edsin Gol) with millions of birds and horses in the middle, and two significant deserts, the Ordos and the GOBI. But the grasses are not guaranteed, having come and gone with changes in climate over the centuries, and making a living off of the land in any one location is less than certain. It is only under the more recent Chinese occupation that cities have even existed, being of little use to the nomadic Mongols, who saw the entirety of the Earth as common ground for their herds.

Today, the region's landscape reflects far more of what has come to be seen as a modern view of development. The area's capital is in Huhhot, a thriving university and manufacturing center just seven hours or so to the west of Beijing. Baotou, just a little further to the west and near the big bend in the Huang River, serves as one of China's major industrial centers for steel and coal production. Although most of the area's residents live in more modern apartment-style housing, it remains common to see Mongol-style circular white tents (*gers*) across the landscape as you move away from the village and town region along the region's southern border with the Great Wall.

Of the area's 23 million residents, 84 percent are Han Chinese, a majority of whom live in the few agricultural zones near the Great Wall or in one of the manufacturing or mining centers. The remaining 16 percent of the population is mostly Mongolians, making the region one of only seven administrative divisions in China where the Han concentration is less than 90 percent.

Moving west from Inner Mongolia, the land gets higher and drier, and the ground has more rocks as we enter the Gobi (literally "rocky desert") until we come to Xinjiang, another of China's autonomous regions. Xinjiang is quite large, roughly three times the size of France but with only 19 million people. Like Inner Mongolia, most of the population lives in a few major cities and around the oases near the Tarim River. The largest city is the region's capital Ürümqi. Another

major city, Kashi (old Kashgar), at the far western end of the basin, served as China's front door along the SILK ROAD for more than 2,000 years. It is also the most distant place on Earth from any ocean. If you were to look down from space, you would see Xinjiang as a group of great desert basins (the Tarim and Dzungar), a smaller basin with the lowest point in China (the Turfan Depression at -505 ft or -154 m), and a towering chain of mountains (the Tian Shan or "Heavenly Mountains") running through the middle. But overall, your impression would be best described using words like *dry*, *barren*, *rocky*, and *sandy*. Because the area contains several basins, there is some water, but most of it disappears into the sands.

The region boasts China's longest inland river, the Tarim (1,300 mi or 2,100 km), flowing from west to east across the northern edge of China's greatest desert, the Taklamakan, before disappearing into the sands near Lop Nor, a large inland lake that looks a lot like a human ear if you see it from space. The Taklamakan Desert in the heart of the Tarim Basin has been famous for centuries because two routes of the Silk Road passed from oasis to oasis along its northern and southern edges. Based on the tales of travelers who heard mysterious noises coming from beyond the high desert dunes or who ventured off the regular path never to return, the local name for this great sand basin translates roughly into "you go in and you don't come out."

The population of Xinjiang has many Turkish-speaking Muslim people similar in culture and language to their counterparts in nearby Soviet Central Asia. The Uigurs (7.2 million) are the most numerous of these groups, and can be found throughout the productive oases. There are also important numbers of Kazakhs in northeastern Xinjiang, and the Kirghiz, who occupy the high mountain pastures of the south-west near Afghanistan.

In the last 20 years, major coal, oil and gas discoveries have been made, but the lack of effective modern infrastructure and lack of transportation connectivity with China's eastern seaboard has made extensive exploitation less than ideal. There are also significant deposits of minerals, especially gold, but as with oil and gas, no serviceable market nor infrastructure to support exploitation. There was a major cotton industry in Xinjiang, but the recent drop in world market prices has caused the government to institute a plan reducing production by 25 percent each year for the next several years. In addition to the railroad from Urumchi to Lanzhou in northwest China, new roads have been

constructed along historic caravan routes, connecting the regional capital of Urumchi with the oil field at Karamai, the ancient town of Kashgar (Kashi), and towns near the Soviet border.

Say "Tibet" and a million different images come to mind. If Xinjiang is famous for its deserts, long forgotten desert cities, and tales of singing maidens hiding in desert sands, Tibet is mysterious as the land beyond the snow, the roof of the world, and more recently thanks to Hollywood, the idea of Shangri-la, that perfect peaceful place where people live forever and there are no wars or conflicts.

This incredibly high, frigid landscape is among the world's most inhospitable places. The land called Tibet (Xizang to the Chinese) is part of a great plateau pushed up as the Indian subcontinent moved into the Central Asian land mass. It is a remarkable highland region that is almost everywhere above 9,840 ft (3,000 m). While the land has wide undulating platforms, numerous snow-capped mountains, glaciers that drain into dozens of long deep valleys, and hundreds of small salt lakes, we as outsiders associate far more with the region's borders that ring with the names of the world's most famous mountain ranges; the Himalayas with the highest mountain on Earth, Mt. Everest (Qomolangma) at 29,028 ft (8,848 m), and the Karakoram, home of the second-tallest mountain, K2, at 28,250 ft (8,611 m). On the southern and northeastern periphery, several of the world's great rivers (Mekong, Changjiang, Huang, Indus, IRRRAWADDI, Salween, and Bramaputra) find their sources.

But aside from all this geographic wonder including Mt. Everest, it is generally Lhasa, Buddhism, and the Dalai Lama that give outsiders a geographic hold on the landscape. These highland peoples have historically been yak herders and nomads, with marginal farming limited to the broader valleys such as the one at Lhasa, where concentrations of people give the area a sense of place. Buddhist monasteries have been at the center of society here for more than 2,000 years, organized by a landowning theocracy dominated by monks. Following contact with the Mongols, the theocracy came to be headed by a Dalai Lama, with the incredible Potala Palace in Lhasa as headquarters. So significant has been the role of religion in Tibet that until the 1950s, one out of every five Tibetans was a Buddhist nun or monk.

Since the early 1950s, the Chinese government has encouraged in-migration by farmers and others, both to stimulate agricultural production and economic development and increase Han presence. But the region's

remoteness and lack of connectivity to other areas in China has greatly limited most of these development efforts. At present, a major railroad line is being built across the frozen Tibetan wastes to Qinghai, where it will connect with the main east-west line to Lanzhou and then eastern China.

### THE SOUTHWEST

Located in extreme southwest China, the provinces of Yunnan and Guizhou could easily be considered part of Outer China, for the area is remote, disconnected from China's core, and populated by minority peoples. But the geography is such that it is a special region unto itself, with major dissimilarities in the core conditions that make it such a unique and interesting place. Just for a reference, you can generally consider the southwest as being south of the Changjiang, with borders with Myanmar, Laos, and Vietnam to the east and south.

Conceptually, the area could be grouped with Outer China in the sense that the high, rugged terrain of the Yunnan-Guizhou Plateau, with its rushing rivers, steep slopes, and lack of connectivity, served as a formidable barrier to entry into China's interior lands. But the region has a long growing season, adequate rainfall for agriculture to exist where the soils are favorable, dense forestlands, and since 1949 improved road and rail connections with the rest of China. The region also grows rice, something we do not see in the dry climate regions that make up the traditional nomadic-pastoral landscape of the four areas in Outer China.

Scattered throughout the plateau are numerous small plains and valleys, called *batze* by the locals, where many of the minority populations live and where agriculture is productive enough to support the 81 million people who now call the area home. But the area's basic remoteness from China's core, mild climate, good rainfall, and adequate food have given the people a laid-back attitude in stark contrast to many of China's other regions, where the pressures of excessive population and inconsistency in food production have made life more problematic until recently.

What is interesting about the southwest is that it is the physical geography that stands out without a dominant place or places around which we could typify the region with a label. And while there are plenty of cities to visit today, they tend to be lost in a landscape whose scenery is rich in picturesque limestone hills with precipitous slopes and overhanging cliffs, beautiful spired columns, giant sinkholes, and caverns with large sub-

*The Chinese landscape varies from frigid mountains to the more tropical yet unique locales (above) in the south.*

terranean rivers often crashing their way through unbelievable rock formations.

In the extreme south where the TROPIC OF CANCER cuts through the southern edge of the plateau, the area boasts tropical forests, banana plantations, elephants, and a host of other jungle creatures unique to all of China. In contrast, you can move to the far northwest and the clouds and mist hide towering 20,000-ft-(6,000-m)-plus glacial mountains and hidden green valleys straight out of the Shangri-la in James Hilton's *The Lost Horizon*.

Both Yunnan and Guizhou have rich minority cultures that make up roughly 35 percent of the population. Of the 43 million people in Yunnan (15 million of whom live in five cities), the Bai, Hani, and Dai are the most numerous, while among Guizhou's 38 million people (with 16 million in four cities), the Miao are the most prevalent.

Yunnan is the most distinctive of China's provinces in that it is home to 20 of the 55 recognized ethnic minorities, something you feel immediately when there. As with the other outer regions, the Han population in the southwest is far less than the 92 percent they average for the country as a whole.

Despite the region's relatively poor soils, important quantities of corn, sweet potatoes, and barley are also produced in the interior valleys and plains. The area is also becoming known as the tobacco capital of China, thanks to the large quantities of tobacco now grown

throughout the plateau's interior hill country and a host of new cigarette manufacturing facilities. Kunming, the capital of Yunnan, is a remarkably cosmopolitan city of 4.5 million, while Guiyang, with 3.4 million people, is the administrative center of Guizhou.

Both were extremely important centers during the Japanese occupation of China in the late 1930s and early 1940s, and both have had significant contact with Westerners over the years. Kunming, in addition to being an important center along the old Burma Road, even served as a base for American flyers (the Flying Tigers) transporting goods during World War II. Aside from agriculture and tobacco, the region has extensive deposits of tin, followed by copper, zinc, and phosphorous.

### THE NORTHEAST

Located in the northeastern corner of China, between the Great Wall and the Russian and Korean borders, are three more provinces whose character has had a long history with China, particularly under Kublai Khan's Yuan Dynasty. China's northeast, or old Manchuria, consists of three provinces, Heilongjiang, Jilin, and Liaoning. Unlike the other lands to the west that are also beyond the Great Wall, the region was subject to Chinese expansion as far back as the 3rd century B.C.E., an expression of the agricultural potential of the Northeast (Manchurian) Plain that occupies the heart of the region.

Today, the region is the most important heavy industrial center in China. It is also one of the more important centers for industrial crops such as soybeans, sugar beets, peanuts, and potatoes in addition to commercial grains such as wheat, corn, and millet. There are significant quantities of coal. Commercial quantities of iron ore exist, but most of it is low to mid-grade. The region also has sizable reserves of molybdenum, copper, lead, zinc, graphite, and bauxite. As China's middle class continues to grow, so has the demand for recreation facilities and resorts.

The heavily forested Hingan Mountains to the west also provide major quantities of timber products in addition to serving as recreational hunting and fishing areas. Because the mountains in the northeast receive significant amounts of snow, the area is also becoming the skiing center of China, with major resorts opening in the mountain areas near Harbin and Jilin. With a combined population of 105 million, the northeast accounts for a little more than 8 percent of China's population, 8 percent of the total land, and interestingly, an 8 percent minority population. But the minority

concentrations get smaller each year with continued immigration by the dominant Han.

### THE NORTH CHINA PLAIN

The North China Plain holds a fascinating presence within the Chinese landscape. It is a special place where history and geography have truly worked together in shaping both the region and the nation as a whole. It is also very clearly a region where the history has also shaped the land. Yes, the region is rich agriculturally, particularly in the central portions where the flat delta plain of the Huang (Yellow) River has provided a broad well-watered setting on which to grow crops for millennia. The landscape is also old in terms of human contact, with archaeological findings such as Peking Man indicating that humans have been in the area for more than 500,000 years. The area is also old intellectually; great philosophers such as Confucius and Mencius expounded their theories on good government here some 2,700 years ago. But of the many geographic features worth describing, none seem equal in dominance to that of Beijing, the region's major city and the nation's capital. It is Beijing and its geography that have so defined what we see today; maybe even for China as a whole.

With a resident population of 11.6 million, Beijing is the center of political power in China. To the casual observer, Beijing could easily be mistaken as another typically cosmopolitan world capital. But the city has had a long relationship with the sea, thanks to the Grand Canal, another of those Mongol creations whose lasting impact is beyond description.

Beijing works closely with the neighboring port city of Tianjin (9 million) less than 100 mi (160 km) away. Although they are separate entities, they should not be considered alone. With a combined population of more than 20 million, independence as national municipal districts, the support of the central government, historic connections to the outside world, and strong connectivity through roads, railroads, and water canals, these two northern giants represent a major driving force within the Chinese landscape and the world.

With Beijing serving as host city for the 2008 Olympics, intense efforts are under way to extend both the city and region's base as the premier economic center in China. The North China Plain is also home to many of China's most recognizable cultural attractions. Among these, the Great Wall at Badaling, the Forbidden City, the Temple of Heaven, and the Summer Palace are World Cultural Centers.

While many foreigners might think Shandong Province is best known for Tsingtao beer, the area contains the home of Confucius and Mount Tai, one of the five sacred mountains in China. To the south in Henan Province are the old capitals of Luoyang and Kaifeng along the banks of the Huang, as well as the mountain stronghold home of the Shaolin monks whose mysterious martial-art form, Wushu (Kungfu), has been turned into countless box office action dramas.

Today, the administrative regions within the North China Plain contain only 5 percent of China's land but have 22 percent of the population. This rather lopsided ratio is possible because the region also has 35 percent of the nation's cultivated land. After centuries of silt deposition from the Huang, the region is covered with a dense carpet of agricultural fields. Although the climate is too cold for rice, the fertile soils are planted with crops such as winter wheat, barley, millet, and sorghum (*kaoliang*).

### THE LOESS PLATEAU

For more than 80 centuries, Chinese farmers have lived and worked on lands of the Loess Plateau. During this time the untold battles and conflicts that occurred shaped a different kind of China. Located in north-central China, the region was the heart of China's first unification as an empire and in some ways a cradle for the great agricultural civilization that followed. Near the outland wastes of the deserts of the far west and the stony steppe of the Mongolian Plateau to the north, this landscape served for more than 10 centuries as China's frontier fortress against foreign aggression.

It is in this capacity as a stronghold against aggression that allows it to be described as a cradle (protector) of China's agricultural civilization. It is also in this capacity and during this specific time that the coevolution of the physical and human Chinese landscapes began. For much of this geographic interplay, few geographic factors stand out more than the area's isolated setting (at the time) and distance from the agricultural core.

But its distance from the heartland and the poor agricultural conditions offered by the Loess Plateau soils were constant challenges to emperors needing to feed an army sufficient to defend the realm. While the LOESS is rich in calcium and thus fertile, the overall aridity of the region coupled with the fact that loess does not hold water makes traditional methods of irrigation and farming useless.

As a result, much of the area has been heavily dissected into "badlands," with rugged hills and gullies

standing out in the landscape, a solemn testament to centuries of repeated misuse and overuse, particularly where there has been extensive cultivation (including terracing) and overgrazing on sloped terrain. The result was that the early Chinese dynasties had to rely on the agricultural heartlands to provide food. It is this extreme cost in food resources that constantly taxed the Chinese system and led to years of internal strife and the possibility of revolt.

Today, the region includes the provinces of Shanxi and Shanxi and maybe even parts of Gansu and Ningxia, but thinking of it as Xi'an and the big loop of the Yellow River is not far wrong. Despite the challenging environment, the region's 70 million people are evenly distributed, following nearly 50 centuries of occupation. The land remains poor agriculturally, and farmers seldom expect to harvest more than two crops every three years. There are still thousands of people living in underground houses dug out of the ground, something the region is particularly famous for.

While severely challenged agriculturally, the region has a wealth of major mineral resources, including vast quantities of coal and natural gas that are only now being exploited as the government works to expand infrastructure in the region. The Huang flows both around and through much of the landscape. But unlike the Changjiang, the Huang freezes in winter and can be navigated only by very small boats and rafts in most locations. There have also been more than 1,500 floods and 26 course changes recorded on the Huang He's journey to the sea during the past 3,000 years. And with each inundation, whether by flood or change of course, there have been heavy losses in lives and property, lending credence to the river's other name as the "River of Sorrow."

### MIDDLE CHINA

Think of middle China and the first thing that probably comes to mind is the Changjiang, the Three Gorges Dam, and maybe by Shanghai and spicy Sichuan food. The words are a perfect beginning to understanding the heart of China. The Changjiang is China's greatest river. Like the Huang, the headwaters of the Changjiang are high in the Tibetan Plateau. But with a catchment basin of more than 700,000 square mi (1.8 million square km), it is more than twice as large as the Huang Basin. Because the Changjiang flows south of the Qinling Mountains, its basin is completely different from that of the Huang.

While the waters of the Huang descend through deserts, loess, and a landscape of prairie grass devoid

of trees and other vegetation, the Changjiang makes its way through a series of basins in what was formerly a region of dense tropical and subtropical forest. Because the region has been agriculturally rich for nearly 2,000 years (with triple rice harvests common), it has long formed the core of the Chinese economy and provided the surpluses in food resources necessary to support growing industrial needs. This is what the great imperial armies worked to protect.

### RIVER BASINS

The basins of the Changjiang, which link together seven provinces and two municipal-class cities, cover about 16 percent of China's land and have 38 percent of the people. The fertile, intensively cultivated lake basins near Wuhan have been called the rice bowl of China, and agricultural productivity is immense.

Population densities easily exceed 1,000 people per square mile (1,600 per square km) in places, with an urban focus on the tricity hub at Wuhan, the site of one of the newest and largest steel complexes in the country and just downstream from the massive Three Gorges Dam. The Changjiang, unlike the Huang, can be navigated as far inland as Sichuan Province, with the huge port city of Shanghai (16 million), near the river's mouth and the largest city on the Asian continent, serving as the gateway to the nation's heartland.

It is on the Changjiang plain that the transition between northern and southern patterns of cultivation occurs (the rice-wheat boundary). Although the transition separates China's cultivated area in half, only one-third of the total agricultural production lies north of the line. South of this division, irrigated rice fields spread out over the lowlands, and tea and other tree crops are planted in the hills. Taken as a whole, the rice-tea agriculture of southern China produces 60 percent of China's food supply on less than half its cultivated area. It also contains a majority of the animal population: half the cattle and two-thirds of the pigs.

The Sichuan (Red) Basin, some 1,000 mi (1,609 km) inland, is an ancient lake that dried up thousands of years ago and has since been filled by ages of erosion and river deposition. The basin is the core of Sichuan Province's 84.6 million people, two-thirds of whom live in the basin proper. Terraced slopes are planted with rice in summer and wheat in winter. At higher elevations, sweet potatoes and corn are grown, with tea and mulberry trees planted on hill slopes.

With 56 percent of the available land devoted to paddy rice, the region is one of the most concentrated rice-growing areas in the world. On the basin's eastern

border are the Wushan Mountains, a remarkably eroded limestone complex that presents a fascinating gateway landscape as you enter the Three Gorges (Sanxia) region of the Changjiang.

### THE SOUTHEAST COAST

Although the area's geography is not well known, mention Hong Kong and most people would indicate some understanding. A few more would think of Hong Kong's sister at the other end of the Pearl River, Guangzhou (old Canton), as the other major city in the area. But why? Despite China's extensive coastline, it has few natural harbors with access to the interior. The Pearl River Delta region happens to be one of the biggest and best adapted.

The region experiences three quite clearly marked seasons, and most annual rainfall falls in the long, hot summer. Temperatures are high enough throughout the year for a 12-month growing period, with rice by far the most important crop. Nearly all the rice grown is freshwater paddy and is at least double-cropped. Other important crops include sweet potatoes, corn, sugarcane, groundnuts, tea, and many other kinds of vegetables. Fruit grows in profusion in this tropical climate. Prominent are the pineapple, citrus fruits, lychee, longan, papaya, guava, banana, and persimmon. Guangdong's silk production is considerable and ranks third behind Sichuan and Jiangsu.

The Pearl River region of Guangdong Province is the heart of China's economic resurgence, with major manufacturing centers in Guangzhou and Shenzhen and outlets for international shipping through the harbor at Hong Kong. Hong Kong is also serves as the regions primary center for finance and insurance.

### MINORITY PEOPLES

China is the most populous country in the world, with 1.3 billion people at the end of 2002, about 22 percent of the world's total. This figure does not include many Chinese in the Hong Kong Special Administrative Region, Taiwan Province, and Macao Special Administrative Region. It is also a multiethnic nation with 56 ethnic groups, the Han being the most numerous, about 92 percent of the population.

The Han people live throughout the country, though mainly on the middle and lower reaches of the Yellow River, the Changjiang and the Pearl River valleys, and the Northeast Plain. Because the Han constitute the major population of China, the other 55 groups make up what are known as national minorities. Although fewer in number, they are also scattered

over a vast area, but are mainly in the border regions from northeast to the southwest. Of these, the Zhuang people from Yunnan, Guizhou, and Guangdong are the most numerous at 15.5 million.

Although the minority groups are numerous, 18 of them account for 94 percent of the minority population. Yunnan Province, home to more than 20 ethnic groups, has the greatest diversity of minority peoples of any province in China.

## choke point

A CHOKE POINT IS ANY narrow passage that restricts traffic. It literally connotes a location where the flow could be choked off. As a military term, it refers to areas in lines of sea, ground, air or space communications (physical travel) that restrict freedom of movement by slowing and confining. This allows an adversary to focus observation, targeting, and engagement assets on a likely area of contact, which can occur at several scales both conceptually and physically at the choke point.

At the tactical level of operations, the spectrum of choke points may array from a doorway of a building, to a bridge across an impassable river, to a mountain pass of some width. As the level of operations expands, then major ports and river valleys add to the array. Globally, major straits, isthmuses, and coastal corridors may "choke" movement of men and materiel at that larger scale of operation.

Maritime strategists have used the concept of controlling choke points as a resource-efficient way to negate the near total maneuverability availed by the open ocean. Transit from world waterway to world waterway is often confined by constricted terrain, be it submerged or above sea level. The BAB EL MANDEB, Straits of Hormuz, Malacca Straits, Cape of Good Hope, Greenland-Iceland-United Kingdom (GIUK) Gap, the Straits of GIBRALTAR, and the English Channel are a short list of the many challenges to any battleship captain. Sir John Fisher, First Sea Lord of the Royal Navy may have coined the phrase "choke point." He proposed that the control of these key locations was central to the domination of the seas and consequently to the welfare of the UNITED KINGDOM.

Commercial concerns arise where natural hazards or accidents could disrupt the flow of goods, particularly oil. Oil transport by tanker is the most flexible means of transport on a global scale. Restricted to a near fixed set of maritime routes because of economic efficiencies, the tankers are vulnerable to a number of choke points. An accident in one of these restrictive passages could cause immediate disruption of commerce and significant financial loss. Be they natural (Strait of Hormuz) or man-made (Suez Canal), they pose a significant risk. However the economic effects must not be overstated in every case. The closure of the Suez Canal from late 1960 until 1975 caused the marketplace to adapt, and the advent of the supertankers brought new economic efficiency along with ecological perils.

Military and commercial operations are now dependent upon space-based assets such as navigational, meteorological, and communications satellites. The concept of choke points is equally applicable to space. Launch restrictions based on Earth rotation, orbit targets, and cargo requirements place spacecraft into a very restricted launch "tunnel" that extends from the fixed site launch facility to its orbital target. Space-based or terrestrial-based military assets could focus on this tunnel for observation and interdiction. Certain points in translunar space, known as lunar libration points, provide physical advantages of a military na-

ture. Basically objects at these locations enjoy a balance of lunar and earth gravitational pulls and can hold position effectively with low fuel consumption. These positions can contest access to and from the moon while dominating earth and moon by observation. They may constitute operational chokepoints.

The term *choke point* has gained wider usage to include any constraining aspect of an operation or process, be it military, business, or academic. It is now being applied to cyberspace when addressing network security and vulnerability.

## Christaller, Walter (1893–1969)

A GERMAN geographer, Walter Christaller helped bring quantitative and statistical disciplines to the study of geography. Christaller was born in Berneck, GERMANY; his father was a clergyman and his mother an author. Before 1914, he attended university in Heidelberg and in Munich. He enlisted during World War I, and became an officer. Returning after the war to study, he went to the University of Erlangen, where he obtained his master's degree in 1930. His doctoral thesis was presented at the University of Erlangen in 1932 under the supervision of Professor Robert Gradmann, a specialist in settlement geography.

Christaller influenced the discipline of geography with the publication in 1933 of his book *Central Places in Southern Germany*, in which he introduced quantitative and statistical techniques for the first time in geography. Between obtaining his master's degree in political economy and conducting doctoral research, Christaller worked in jobs as a journalist and also as a miner.

Christaller's work followed several theoretical works that started in the 19th century and aimed to determine the optimal location of an economic or a geographic entity in a given environment. This followed from works by economists (Johann Heinrich Von Thü-

nen, Andreas Predöhl, William J. Reilly, August Lösch), sociologists (Alfred Weber, René Maunier), engineers (Leon Lalanne, Jean Reynaud), and a geographer (Johann Georg Kohl). Jean Reynaud had already initiated his stream of research in an article entitled "Cities" in *l'Encyclopédie nouvelle* (1841) and proposed an elaborated version of the theory of central place. The double formation of Christaller as a geographer and an economist could explain the elaborated graphics and cartographic expression in his research.

His field survey in southern Germany, which at that time stretched from the Alsace region to AUSTRIA, permitted him to develop his theory. In the 1930s, this region was little affected by the INDUSTRIAL REVOLUTION. As a result, the model postulated that the organization observed was the product of market and rural logics.

Christaller developed the idea of a space that is supposed to be isotropic, homogenous, and functioning in self-sufficiency in perfect conditions of competition from economic agents, producers, and consumers. Christaller graphically showed interests convergent with the general interest in a regulated society, representing hexagonal market areas that are fitted in each other to cover all the territory. Central places emerge at the center of each hexagon, which contained six lower-order places to ensure that goods and services are available. His model, based on a hierarchical central place system, suggests four basic premises.

First, the higher-order central places will provide all goods and services that are found at the lower-order centers. Second, larger central places will provide a variety of functions and specialized functions. Third, within a place, the number of lower-order centers will be proportional to the number of higher-order places; and fourth, the higher-order central places have greater distances between similar places compared to lower-order places, because of the exclusivity of market boundaries.

The Christaller Model inspired leaders of planning in the national-socialist state and the practices of town and country planning in several countries. Christaller could use his theory in practice with the rise of Adolf Hitler's Third Reich in Germany and its conquered territories, including a reconfiguration of the geography of Germany's eastern conquests such as Czechoslovakia and POLAND. Particularly in the priority plan *Deutscher Osten*, Christaller was in charge of planning for occupied Poland by using his central place theory. The model of central place was improved in 1940 by the economist August Lösch, who was far less inclined

to the ideas of the Reich at that time, with the introduction of theorist postulates influenced by the classic economic approach. The honors to Christaller's achievements came at the end of his life and include the Outstanding Achievement Award from the Association of American Geographers in 1964. In 1996, the Geography Award of Walter Christaller was created in Germany. This award, a reference to the international prestige of the geographer, but not as his past experience as a planner of the Reich, has fueled debates in the German geography community.

## Christmas Island

CHRISTMAS ISLAND IS AN isolated island in the INDIAN OCEAN, located about 220 mi (360 km) southwest of JAVA, INDONESIA, and 1,400 mi (2,300 km) northwest of AUSTRALIA, to which it belongs as a dependency. Maintained chiefly as a phosphate-mining colony since the 19th century, it is now being developed as a tropical island holiday spot and as a potential launching site for the Asia-Pacific Space Center.

The island is the summit of a submarine mountain. About 60 million years ago a volcanic cone emerged, became covered in coral and limestone, and sank back into the sea, only to reemerge from tectonic uplifts about 10 million years ago. Coral reefs surround the crown of this peak. It is evident that this is the top of a mountain because there is virtually no continental shelf: the surrounding waters plummet to 1,650 ft (500 m) within 660 ft (200 m) of the shore. Sea cliffs up to 60 ft (20 m) rise straight from the sea toward a central plateau. There are a few shallow bays, the largest being

the island's only port, Flying Fish Cove, on the northeast corner. Most of the island is covered by tropical rainforest, which, since 1998, has been preserved as a national park. This park attracts visitors to its unique flora and fauna, notably the island's most famous residents, the red crab: 100 million of them crowd the forest floors. The surrounding waters are known for their varied tropical fish, spinner dolphins, and the occasional whale shark.

The island was noted in the logs of various British and Dutch explorers in the 17th century and given its name by one of these on Christmas Day, 1643. The uninhabited island was annexed by Great Britain in 1888, and some settlers arrived from the COCOS ISLANDS (560 mi or 900 km to the southwest) to collect timber and supplies. Phosphate mining began in the 1890s, with imported labor from Southeast Asia. Today's Chinese and Malay populations are descendants of these workers and are the bulk of the island's population. The island was administered as part of the Singapore Colony until 1957, when Australia bought it for £2.9 million. The mines closed in the 1980s, so Australia granted citizenship in 1984, giving its residents social services and emigration possibilities. The mine was bought by locals in 1991 and reopened on a smaller scale, but government-sponsored tourism is now the largest industry, including a casino.

## city types

CITIES ARE INFLUENCED by a broad variety of contexts and factors, including particular groups of people. As a consequence of numerous influences, the city may, to some extent, specialize in and be characterized as being of a particular type. To refer to people and government regimes, for example, a number of particular city types can be observed, such as aristocratic, democratic, oligarchic, and dictatorial. These types of regimes can be employed to classify city types developed under their orders.

The types of specialization that occur within an urban center are widely used to classify city nature or

type. For instance, cities that contain a manufacturing industrial base are commonly referred to as industrial cities, while cities that act as markets with the buying and selling of particular goods are sometimes known as market cities or market places. Other means by which cities can be classified include art, culture, and size. Demographic size is an important criterion in the categorization of different urban places. Urban centers have consisted of an order based on population size, starting with hamlets, then progressing in size and spatial extent to villages, towns, and cities.

However, in the modern era, many cities in the world are so large and have such important functions (principally economic and political) that they are referred to as world cities. Places noted as being world cities in the past are not necessarily world cities of the modern age. Some world cities in history, such as Bruges in BELGIUM, are not world cities today because of their stagnation in size, their decline in importance, and the rise of other urban places. If the modern period is considered, world cities are principally classified by their market and industrial functions.

For example, arguably the first modern world city was LONDON, England, a settlement that grew from about one million people to over 6 million people between 1801 and 1901, as a consequence of its rapidly expanding economic base brought about by the forces unleashed by industrialization. Today, places that are considered world cities include TOKYO, NEW YORK, London, and PARIS. However, other places are also acknowledged as being significant settlements in the global context, and these places include MEXICO CITY, Sydney, Cairo, and MUMBAI—a consequence of their large size, diversity of population, international financial institutions, and stock exchanges as well as a variety of internationally known cultural institutions and landmarks.

In noting city types it should be specified that classifications vary significantly from country to country and that even within a country city types can vary. For instance, in CALIFORNIA, city types are noted according to their local governments and the range of freedoms that these municipal authorities enjoy. Thus, in California, cities are classified as being either charter cities or general law cities, depending on whether or not they operate within the framework of California municipal law.

At different times in history, cities have been developed in response to different functions and influences. One of the most significant periods of societal development was the Renaissance, and during this time a

whole new city form was developed. This new city, known as the Ideal City, was to be based on the application of a strict geometric (circular) form around which was placed a wall for defense. Notable examples of ideal cities include Palma Nuova in ITALY, although arguably the most famous, Sforzinda (designed by the architect Filarete), was never actually built. While in the context of the Renaissance the ideal urban place could be noted for its particular morphology, in subsequent times, other ideal city types were more renowned for their open, democratic, and civilizing societies. These include places such as the first garden city, Letchworth in England, which was created in 1904 as a place to create a community where the poor could live as well as the rich within a low-density environment filled with gardens and foliage.

Other modern ideal city types include Chandigarh in INDIA, the brainchild of modern architect pioneer Charles-Édouard Le Corbusier, and Putrajaya in MALAYSIA, a late-20th-century urban project to create an administrative center within the Federation of Malaysia, and thus to leave the county's capital, Kuala Lumpur, to specialize in commercial and financial activities. Following the successful development of Putrajaya, the Malaysian government created a new urban place called Cyberjaya, a new city type, a cybercity, where the world's most advanced information technology companies are to be based within a low-density, tropical-inspired landscape.

## city-states

A CITY-STATE IS AN independent political entity composed of a large and important town and surrounding countryside. In ancient times, city-states, such as the Greek city-states and Rome, sometimes became great economic and military powers that secured far-flung empires, thereby imposing their will and culture on other civilizations. In late medieval and Renaissance ITALY, powerful trading city-states flourished such as Florence, Milan, and Venice. City-states also

existed in northern GERMANY at Bremen and Hamburg. Some contend that city-states exist today and new forms are emerging that exhibit economic power and independence if not the political sovereignty of earlier classical examples.

The first city-states were in Sumer in the fertile lower Tigris-Euphrates Valley of Mesopotamia. The open area was vulnerable to invasion, but the Sumerians found strength in their urban units. Important cities were Akkad, Eridu, Kish, Lagash, Larsa, Umma, Ur, and Uruk. Rulers of the most important Sumerian cities were periodically able to assert their control over the region.

The city-state reached its zenith in ancient GREECE. Although sometimes able to form federations to face a common foe like Troy and Persia, the Greek city-state, or *polis*, remained the form of social structure. The most significant were Athens and Sparta. Of lesser importance were Argos, Corinth, and Thebes. Within these cities, different forms of government were tried, such as monarchy (hereditary kingship), tyranny (dictatorship), timocracy (rule by the wealthy), oligarchy (rule by a few), and democracy (rule by the people [free male citizens]).

One of their greatest achievements was democracy, which until the late 18th century was believed feasible only in city-states where people could easily meet and reach community decisions. Though disunited and small in territory and population, the Greek city-states contained fiercely patriotic and creative citizens. Their cities became the cradle of Western civilization with monumental achievements in art, literature, drama, history, architecture, science, and philosophy. The Greeks spread their rich culture by founding new and significant city-states throughout the Mediterranean region. Greek colonies appeared at locations as diverse as on the shores of the BLACK SEA, present-day FRANCE, Africa, Asia Minor, Sicily, and Italy.

It was from a small city-state in Italy that the world's greatest empire arose. Legend says that the city of Rome was founded by its first king, Romulus, on the Palatine Hill on the Tiber River. The Roman Republic was born when the rule of Etruscan kings was overthrown in 509 B.C.E. Despite a vulnerable geographic position, the empire won by its energetic and ambitious citizens would be of unrepresented durability, might, and size as it stretched from Scotland to Persia.

Eventually the republic, governed by a senate, would be replaced by the rule of emperors following the rise to power of Caesar Augustus, and the city of Rome would become a crowded metropolis of tower-

ing marble structures such as the Colosseum. Wherever the Roman legions marched, they brought not only Roman rule, but law, order, economic unity, trade, and massive public works. Rome was also unique in the liberal granting of Roman citizenship to conquered peoples across the empire, but it also brought oppression and slavery. Rome's greatest contributions to Western civilization were law, public administration, urban planning, military strategy, literature, and architecture. The Western Roman Empire eventually succumbed to a slow decline, the causes of which are still debated. The Goths would depose the last emperor in 476 C.E.

The disorder of the Holy Roman Empire led to the formation of independent towns and principalities in northern Italy. The three most important city-states were Florence, Milan, and Venice. Lesser city-states included Ferrara, Genoa, Lucca, Mantua, Padua, Pisa, Siena, and Urbino. The Italian city-states, the kingdoms of Naples and Sicily, and the Papal States constantly engaged in wars and intrigues, thereby producing ever-shifting borders and alliances.

Eventually, some city-states commanded enough territory and wealth to become major European powers and centers of culture and learning as their plotting princes and ruling families helped fuel the Renaissance by patronizing the arts. Most of these city-states began with an adherence to republican ideals but degenerated into ruthless oligarchies and despotism, but often with a façade of republican institutions.

After defeating its rival, Genoa, Venice emerged the most republican and successful Italian city-state in amassing riches through trade and in avoiding the endless conflict suffered by the others. Yet the cities' sovereignty was lost in the 19th century through infighting and the inability to unite against outside aggression. The Black Death also took a horrendous toll on their dense populations.

Today, SINGAPORE ("the lion city") and HONG KONG are often viewed as modern city-states exerting enormous economic power and political independence, although the extent and future of Hong Kong's quasi-independence from CHINA is in question. Less convincingly, some contend that other large cities may develop into city-states because of their economic influence, such as LONDON, LOS ANGELES, NEW YORK, Rotterdam, and TOKYO. Yet these and other large urban centers, with international trade and ties, are firmly a part of their nation-states, with neither a prospect nor a desire of gaining the political independence or sovereignty sufficient to qualify as true city-states as traditionally defined. Nevertheless, many large cities are

gaining greater independence in managing local affairs and international economic activities.

More futuristically, some assert that “Dubai Internet City” in India is destined by design to become a completely new type of city-state for the 21st century as it strives to reach its goal of becoming an independent and principal ground base for the cyber-world economy, thus substituting communication and corresponding economic centralization for geography as defining characteristics of the city-state. Also predicting the future, some economists argue that the forces of globalization or regional economic and political unification will eventually make cities more important than nations. Some envision this happening to cities in the center of Europe, such as Lyons, Stuttgart, Milan, and Barcelona, if the EUROPEAN UNION strengthens and blurs national distinctions. Therefore, the definition of a city-state may ultimately change to reflect traditional economic independence, but with new forms of political autonomy and perhaps transcending traditional geographic boundaries.

## civilizations, early river

Early river valley civilizations arose in Mesopotamia, EGYPT, the INDUS RIVER Valley, and CHINA. Earlier agri-cultural societies (8,000 to 13,000 years ago) were largely subsistence cultures. The river civilizations had food enough to provide for classes of people other than just farmers. These societies all used agricultural sur-pluses to establish civilizations with cities and trade and to create greater sophistication in the arts, sci-ences, government, and even a leisure class. Cities en-abled societies much more sophisticated than primitive agriculture allowed. The first beginnings of a higher-

level urban-rural society began in Mesopotamia about 4000 B.C.E. The other civilizations appeared shortly thereafter.

### MESOPOTAMIA

Mesopotamia, “The Land Between Two Rivers,” lay in the valley of the Tigris and Euphrates rivers. The rivers provided fish and birds as sources of food. More im-portant, they made agriculture relatively easy. The land lacked a dependable supply of rain, and the supply from the rivers was variable through the seasons. With careful irrigation, the water from the rivers allowed the fertile land of Mesopotamia to produce crops larger than the farmers needed to subsist. Cities do not pro-duce primary products—they refine basic materials. Cities were vital for trade, handicraft production, gov-ernment, and military defense.

Sumerian civilization dominated Mesopotamia from 3500 B.C.E. to 2000 B.C.E. It was replaced by Babylonia, then Assyria. Sumerian city-states prolifer-ated between 3200 and 2350 B.C.E., dominating their regions. Cities provided order and a mechanism for handling public projects. The cities collected the wealth of their outlying agricultural regions: barley, dates, wheat, vegetables, and livestock. City merchants traded textiles and other products for luxuries such as ivory from PERSIAN GULF peoples.

Each city had its own god. The central structure in the fortified city was the temple to the city’s god and protector. Architectural highlights include the ziggurat, a large and aesthetically impressive temple tower and house of god made of mud brick, built as a form of worship. City administration was initially by assembly, but by 3000 B.C.E., kings ruled the city-states, the sin-gle head being more efficient when action was neces-sary. The king ruled over the city and its hinterlands, which received defense in return for agricultural prod-ucts that allowed the kings to establish militaries, tax collectors, administrators, and the leisure class.

Sumerians were the first to use bronze. They also made pottery and carved stones and shells while creat-ing gold and silver jewelry. Sumerian pictographs evolved over the centuries into cuneiform. Sumer fell to the expansionist urges of Sargon of Akkad (2370–2315 B.C.E.), whose empire lasted until circa 2100 B.C.E. Babylon was a successor to Sumer, dominating until around 1600 B.C.E. Babylon used Sumerian irrigation and agricultural technology and the Sumerian calendar. Babylon developed a number system based on six and worked with perfumes, cosmetics, medicine, and phar-macology.

Hammurabi's *lex talionis* was the first written code of laws. The civilization collapsed when the Hittites invaded around 1596 B.C.E.

The third major city civilization, Assyria, was expansive. The Assyrians were immigrants who came in two waves, around 6000 B.C.E. and in 3000 B.C.E. They spread from the Tigris to the Armenian mountains in the north and the ZAGROS MOUNTAINS in the east, developing mining and forestry. Assyria established a few large cities for trade and crafts development, but it was mostly small villages with irrigated farms. Assyrians were organizers and warriors.

The Mesopotamians early on lacked systematic laws, didn't use analogy, and had limited science. But they had high-value literature, prime examples of which were the creation myth, *Enuma Elish*, and the epic, *Gilgamesh*. The *Code of Hammurabi* exemplifies the writing of law. Mesopotamia was deficient in stone and wood, which it had to import, but it had clay, which served for writing tablets as well as houses.

The religions of Mesopotamia were polytheistic, with multitudes of temples to the multitudes of gods. The beliefs would later influence the Hebrew and Greek religions. Accomplishments of this civilization included the wheel, used in carts, the arch and the dome, cuneiform writing, astrology, and a number system based on 60.

Mesopotamia was an indefensible and rich region without natural barriers—mountains and rivers—to keep out potential enemies. Many times in its history, a dynasty crumbled before the onslaught of a foreign invader. Dynasties lasted normally only a few hundred years. Although cities did slow the attackers because they were fortified and thus defensible, the cities were more important in providing the setting for the development of sophisticated societies with long-lasting cultural legacies.

## EGYPT

Egypt had but a single river, unlike Mesopotamia, but it was equally dependent on its flow. The NILE floods annually, restoring the fertility of the soil on its banks, the basis for Egyptian agriculture in a desert environment. Agricultural settlements appeared along the Nile around 4000 B.C.E. The towns flourished because they were protected from invaders by the RED and MEDITERRANEAN seas and the deserts.

Egypt had only a few hundred thousand people in the Predynastic period, 5000–3000 B.C.E. By the Old Kingdom, c. 2575–2134 B.C.E., the population was 2 million, which grew to 7 million at the time of annexa-

tion by the Roman Empire. In 3100 B.C.E., Menes (Narmer) unified Egypt, establishing his capital at the new city of Memphis. From there he ruled a centralized state. He was pharaoh, or king of Egypt. The pharaohs built pyramids as symbols of their power and authority, in life and after. The pharaoh's greatest power came during the Old Kingdom, and the greatest pyramids were built during this era. At Giza is the largest of the pyramids, that of Khufu (Cheops).

The Egyptians were also polytheistic. Their principal god was Amon-Re, and they had a strong cult associated with Osiris. The cult believed in immortality, so logically they wanted their bodies to last forever, thus they developed mummification. The society was hierarchical, with the pharaoh as supreme head of society. There was also nobility, but the bureaucracy and military were more important. Other classes included priests, commoners, and slaves. Egyptians wrote in hieroglyphics on papyrus. They had skilled architects and engineers, doctors and mathematicians, and education was a path to being a scribe, a highly regarded job. Their calendar rested on observation of the movements of the stars and sun.

The Egyptian economy was predominantly agricultural, depending on the Nile, which also provided fish and birds. Crops included emmer (wheat) and barley for bread and beer, as well as vegetables and fruits. Post-harvest fields provided forage for cattle, sheep, and other livestock, which provided meat and dairy products.

Egyptian tools were simple—hoes, sickles, and the like, with plows drawn by cattle or oxen. Associated industries were wine and beer making, textiles, leather, pottery, baking, and woodworking. The exchange of goods and services was by barter because there was no monetary system.

Taxation was heavy. Egypt also mined and worked metal—gold and copper. Their bronze age began around 1500 B.C.E., and iron smelting began around the 6th century B.C.E. Stoneworkers quarried and worked limestone, calcite, granite, and diorite using bronze tools. They also mined minerals and semiprecious stones. Because wood was scarce, Egypt traded emmer, gold, and other items for it. They traded with NUBIA and southwestern Asians in SYRIA, Mesopotamia, and Canaan.

Alexander the Great conquered Egypt in 330 B.C.E., but his empire crumbled quickly after his death, with the Greek Egyptian Ptolemaic dynasty lasting until late first century B.C.E., when Cleopatra asked Rome into Egypt.

## INDUS RIVER VALLEY

The Indus River flows from a source in the HINDU KUSH and HIMALAYAS. It is unpredictable, like the Nile, and like the Nile, it deposits rich silt that keeps soil fertility high, allowing agriculture to thrive. The first crops cultivated in the Indus Valley were barley and wheat. This civilization also domesticated the chicken. Although Paleolithic communities had existed 200,000 years ago, and Neolithic communities from 8000 to 5000 B.C.E., complex society arose between 3000 and 2500 B.C.E.

The Indus Valley civilization prospered on the river plains and vicinity in what is western INDIA and PAKISTAN. About 2600 B.C.E., the early cities began to interact, creating a common urban culture that lasted about 700 years. The inhabitants were known as the Harappan or Indus culture, and it thrived contemporaneously with those of Mesopotamia and Egypt. Each of the societies had its unique art, technology, and social arrangements because each developed from a different Neolithic community that existed in the area until around 6500 B.C.E. The civilization extended from the mountains of AFGHANISTAN and BALUCHISTAN to Gujarat, Makran, and Sindh on the coast. At its peak this civilization traded with the other cultures on the Arabian Gulf, peninsular India, and West and Central Asia.

Two cities, Harappa and Mohenjo-daro, dominated. Each was fortified and supplied its citizens from a large granary. Having political and economic control, each was a seat of authority, a distribution site for the outlying region. The two cities may have served as co-capitals of the civilization. They did provide extensive development of the human aspect of the city—broad streets, marketplaces, temples, and diverse other public buildings.

The civilization developed standardized weights and measures as well as standard brick sizes and styles of architecture. It had specialized labor in pottery tools and decorative objects. It also engaged in trade with Mesopotamia from 2300–1750 B.C.E. India traded copper, ivory, and pearls for Sumerian wool. Other trade was in metals—gold, silver, copper, lead.

In Harappa, social status was shown by style of living, with clear differences between rich and poor. The religion was strongly based on fertility. The society began declining around 2000 B.C.E. because of deforestation, erosion of topsoil, and a general ecological decline that reduced the agricultural surplus, bringing on a problem of subsistence within the society. Also plaguing the civilization were a series of floods and earthquakes. The abandonment of the cities began

around 1700 B.C.E., and the civilization collapsed within 200 years, by 1500 B.C.E.

## CHINA

Chinese history records a cultural change under the leadership of three legendary persons around 2800–2600 B.C.E. Fu His gave China hunting, fishing, trapping, and most importantly, writing. They got agriculture and trade from Shen Nung. And government and Taoism came from the Yellow Emperor (circa 2700 B.C.E.). After that, the Chinese enjoyed enlightened rule by the three Sage Kings: Yao (around 2350 B.C.E.), Shun (around 2250 B.C.E.), and Yu (rule began in 2205 B.C.E.). After this, history being cyclic, from perfect wisdom and virtue the course of human events decayed.

China's early agricultural civilization arose under the Xia dynasty near the southern bend of the Huang (Yellow) River, which has its source in Tibet. Chinese agriculture began near the southern bend of the Yellow River approximately 4000 B.C.E. Initially the agriculturalists grew millet, but later they began growing rice near the Huai River to the south.

Neolithic societies arose after 5000 B.C.E. This was a stone-tool culture, tribal with some domestic animals but relying on hunting also. Some made fine pottery and bone tools. Presumably they engaged in intertribal wars and worshiped ancestors in some fashion. Neolithic China was a time of female rule, but the creation of complex large city-states resulted in a switch to a patriarchal society.

The Huang River is yellow because it contains suspended fine loess. It is “China's Sorrow.” Like the other nutrient-rich rivers, it floods periodically, bringing devastation. As people concentrated together, the need arose for authority to preserve order, settle disputes, and create public works. The Xia dynasty was the first effort to do this. Established in 2200 B.C.E. by Yu, it set the precedent for rule by a hereditary king. It also established flood control and political institutions. The central authority controlled the village leaders. It also emphasized metallurgy and the founding of additional cities as the population spread.

Between 1766 and 1122 B.C.E., the Shang dynasty controlled the area. It originated south and east of Xia. Its agricultural surpluses allowed it to maintain a large army. It moved its capital six times, but it left an extensive written record as well as material remains, including weapons and chariots in its lavish tombs. Next came the Zhou dynasty, which arose in the west, where the Shang lacked control. Because the final Shang was

a criminal, the Zhou unseated him in 1122 B.C.E. The Zhou introduced the idea of the mandate of heaven, the Right to Rule. They tied earthly events to Heavenly affairs. Divine mandate validated the Zhou claim to the throne because only virtuous rulers received the mandate. The Zhou king was titled “Son of Heaven.”

The early dynasties ruled through family and kinship groups. Worship of ancestors was integral. The belief was that the ancestors remained present and able to influence worldly affairs. The dead were buried with material goods, and the head of the family presided over the rites. Socially, the culture was stratified, with the royal family and nobility on top. Hereditary aristocrats had large holdings of land. Artisans and craftsmen were a small percentage of society, and some worked only for the ruling class. Merchants and traders went south and west, seeking jade from central Asia or military technology from Mesopotamia. The peasant class served in the military or worked the land or provided general labor for the ruling class. In return they received land to work. They lived underground. Women made wine, wove, and cultivated silkworms. Slaves performed the hardest labor; they were generally prisoners of war. Chinese culture was secular. There was no organized religion. Fortune-tellers used oracle bones to predict the future. Early Chinese writing was in pictographs. It developed to ideographs to handle complexity and abstraction. It had over 2,000 characters but no alphabet or phonetic element.

JOHN BARNHILL, PH.D.  
INDEPENDENT SCHOLAR

ature, precipitation, cloud cover, air masses, atmospheric pressure, winds, and cloud coverage. Of these, temperature and precipitation are the most important factors in establishing climate type. A place may have rain on one day, clear conditions for a week, and then have cloudy skies the next day followed by a hailstorm. The conditions described here would certainly be familiar to a resident of the Midwest in the United States. Daily weather variability in any given place may be quite dramatic. Or the weather may be predictably uniform from day to day. The equatorial regions exhibit this kind of weather: warm temperatures, afternoon showers, slightly cooler nights, and then the repeat of the preceding day’s weather.

Whether the daily weather occurrences at a place are extremely variable or predictably uniform, it is the long-term averages of the weather factors that will be used to determine the climate of a place. Scientists in early GREECE devised a very simple and straightforward climatic system for the Earth, as they knew it. The system was composed of three zones or *klimata*. The zone occupied by the Greeks and other culture groups living near the MEDITERRANEAN SEA was called the Temperate Zone. This zone had temperature and precipitation values that made it ideal for human occupation.

To the south of the temperate zone was the Torrid Zone, an area simply too hot and debilitating for humans to survive. At the time of the development of this climatic system, no one from the temperate zone had traveled very far to the south and certainly not to the equatorial area. Consequently, a great deal of speculation centered on the region and what manner of protection any inhabitants would have to ward off the blistering rays of the sun. There was conjecture that a resident in this region would have feet large enough to extend over his head umbrella fashion to block the sun’s rays.

To the north of the Temperate Zone was the Frigid Zone, the unexplored area too cold for humans to survive. As simplistic as this three-zone system may sound today, it was nevertheless based on sound logic: Places to the south of the Greek homeland are warmer and places to the north are colder. These are true observations. However, today we can add immeasurably to the descriptions of our climatic systems and refine them to take into account even subtle changes from place to place.

## CLIMATE SYSTEMS

The climatic system most used in geography and climatology is the structure devised by Vladimir Köppen, a

## climate

THE TERM *climate* refers to the long-term averages of insolation (solar radiation absorbed by Earth), temper-

German climatologist and botanist. Köppen worked with his student Rudolph Geiger on the development of a climate map of the world first introduced in 1928. Although the formal name of the system incorporates Geiger's name (Köppen-Geiger), we know it today simply as the Köppen climatic system. Köppen's system uses capital letters to designate latitudinal bands from the equator north and south to the poles. A second, and in some cases a third, letter is added to distinguish differences within a main category. The primary capital letter designators are as follows:

- A Tropical climates
- B Semideserts and dryland climates
- C Humid mid-latitude climates
- D Humid continental climates
- E Polar climates
- H Highlands

The "A" climates are found along the equator and are further designated as "Af," or tropical rainforest, and "Aw," or savanna (tropical grasslands). The "B" climates lie north and south of the "A" climates. The "B" climates are further designated as "BS," or steppe (dryland grasses) and "BW," or deserts. The mid-latitude climate designated with "C" has three subclimates. This is a tipoff that there is greater weather (and climate) variability in the mid-latitudes than in any other region in the world. The "C" climate is further designated as "Cs," or Mediterranean climate, "Cfa" or humid subtropical, and "Cfb," or marine west coast.

It is interesting to note references to actual regions in the designations of some subclimates. For instance, Mediterranean climate regions are found on the West Coast of the United States, the coast of Chile, east of the Mediterranean Sea to Central Asia, and along the southern coast of Australia. These places are so designated because the climate found at their locations is identical to the climate of the Mediterranean region.

The "D" climates are next. They are designated as "Dfa," or humid continental with a hot summer, and "Dfb," or humid continental with a very cold winter. The "E" climates are found in the polar regions. "ET" refers to both the subarctic and tundra climates. "EF" identifies the ice caps on both the ARCTIC OCEAN and the extensive sheet ice that covers the land area of ANTARCTICA.

One major climatic region remains: the "H," or highlands climate. This climatic region is sometimes referred to in the geographical literature as the undiffer-

entiated highlands climate because the mountainous areas in which it is found have such steep gradients that several climate types may exist over relatively short distances.

## CLIMATE PATTERNS

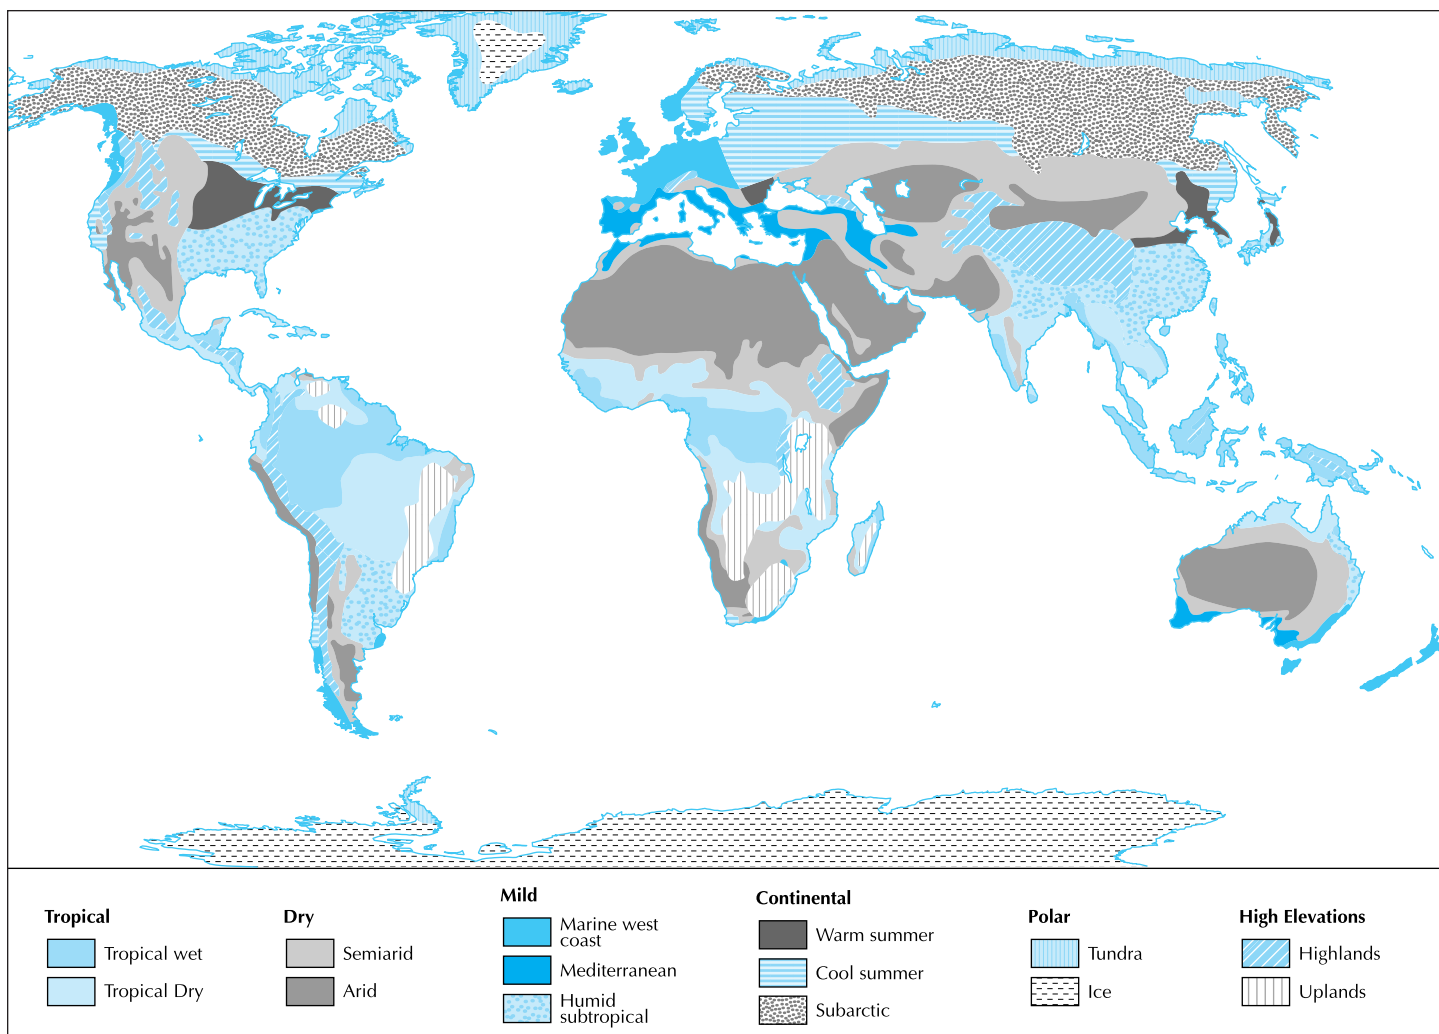

The patterns of climate on the Earth's surface are displaced by latitude north and south from the equator to the poles. Tropical rainforests straddle the equator in South America and Africa and extend to the coastal areas of MADAGASCAR, INDIA, Southeast Asia, and AUSTRALIA. This is a warm and wet climate throughout the year. A climograph of the region would exhibit fairly even temperatures throughout the year and significant rainfall in every month. The equatorial belt is the destination for the converging trade wind coming from both the Northern and Southern Hemispheres. These winds reach the equator and are lifted to high elevations, where condensation occurs and rainfall is produced in abundance.

The savanna regions lie astride the tropical rainforests. They are warm and moist, but their rainfall is seasonal. Consequently, the moisture received in the savannas will support grasslands and some trees but not the density found in the tropical rainforests.

The "B" climates are dry. Their dryness may be due to their leeward locations on mountainous terrain or a latitudinal location far from moisture-bearing winds. The "B" climate produces either steppe (dryland grasses) vegetation or true desert. Bands of steppe and desert are found in North Africa and the west coast and interior of southern Africa and within the Rocky Mountain and Basin and Range Provinces in the United States and MEXICO. The "B" climate is also found in extensive areas of Central Asia, northern China, and eastern SIBERIA. Nearly all of Australia is in the "B" climatic zones, the interior of this continent being desert.

The "C" climates are found in large areas in the Northern Hemisphere and to a lesser extent south of the equator. This fact is readily apparent with one glance at a globe. South of the equator, the land areas begin to dissipate rapidly. There is room for a bit of each of the Mediterranean, humid subtropical, and marine west coast climates in southern South America and southern coastal Australia. The very southern tip of South Africa has a mere touch of Mediterranean climate and a bit of the marine west coast.

In the Northern Hemisphere, large expanses of humid subtropical are found in a band from northern India to southern China and again in a large section of

*The display of climate regions on maps helps geographers understand the location of other environmental features that climate influences. Such climate-related features include water, vegetation, soils, landforms, and wildlife.*

the southeastern United States. The Mediterranean climatic zones, already discussed, are found on the West Coast of the United States and along the Mediterranean Sea and east to Central Asia. Marine west coast climate is found on the west coast of the U.S and extensively within the European LITTORAL and the eastern and southern expanses of the Scandinavian Peninsula.

The “D” climates do not occur in the Southern Hemisphere. In order for a “continental” climate to develop, there must be a large land area within the mid-latitudes. This is simply not the case in the Southern Hemisphere. So, the “D” climate is unique in that it exists in only the Northern Hemisphere where it is found in extensive areas of North America and Asia. The “Dfb” continental climate has warm summers and very cold winters. As such, the range in annual temperatures

is greater than any other climate. It is not uncommon for the temperatures in northern MINNESOTA to reach 90 degrees F (32.2 degrees C) in summer and 35 degrees F below zero (-37 degrees C) in the winter. The interior of eastern Siberia has even colder winters. Verkoyansk, a city in eastern Siberia, is called the cold pole of the Northern Hemisphere with record winter temperatures reaching 120 degrees F below zero (-84 degrees C).

The “E” climates are limited to the polar regions. In the Northern Hemisphere, large expanses of subarctic and tundra climates may be seen. *Tundra* is a word that designates a climate in which trees cannot grow. The boundary, then, between the subarctic and the tundra to the north is the tree line. Beyond the tundra to the north is the ARCTIC OCEAN, ice-covered most of the

year and carrying the climatic designation of “ET” or ice cap. In the far polar reaches of the Southern Hemisphere, only a sliver of tundra climate is seen on the Antarctic Peninsula as it juts into the ATLANTIC OCEAN south of Tierra del Forego. The only remaining climatic zone in the Southern Hemisphere is the vast ice cap covering ANTARCTICA, a sizeable “ET.”

### EFFECTS ON GEOGRAPHY

The climates of the world influence human occupants in innumerable ways. Combinations of temperature and precipitation will impact agricultural systems and dictate the types of crops that can be efficiently grown. People living in the tundra will dress quite differently than the resident on the shores of the BLACK SEA. And there will be little use for snowplows in Miami, FLORIDA; but there had better be a number of them on hand when winter reaches Buffalo, NEW YORK.

However, the commenter on climate must resist the temptation to say that the climate determines the kinds of activities that the human occupants may engage in. To do so would be to invoke the short-lived geographical theory of environmental determinism. This theory held sway in American geography during the first two decades of the 20th century. Simply stated, environmental determinism held that the environment, especially the climate, of a region determined the activities of the human occupants. It left no room for advances in technology or the ingenuity of the human occupants to overcome environmental limitations. This theory was eventually put to rest in favor of a more flexible view of humans and their environment and the realization that human-environment interaction is a two-way street.

One of the regions in which agricultural origins have been traced is the highland area north and east of the valleys of the Tigris and Euphrates rivers. This highland area contains a great number of individual microclimates in its valleys and slopes. Variegated regions such as these allow for the growth of multitudes of plants within a limited area. Strains of wheat and other grains grew in these physical recesses and were eventually discovered by the wanderers and gatherers populating the region. When it was realized that seeds from the plants in the ground would produce a new plant, agriculture was originated.

Climate is explained best as the combination of primarily temperature and precipitation over a long period of time. There are also examples of how the shape of climate regions can impact agricultural activity. The large and productive agricultural region in North

America has a unique areal combination of temperature and precipitation. Temperature decreases from south to north in the vast interior basin of the United States and southern CANADA. Precipitation, on the other hand, increases in an east to west direction from the ROCKY MOUNTAINS to the eastern seaboard.

The result of these patterns is the creation of an almost infinite set of microclimates with their own unique temperature and precipitation regime, an ideal setting for the growing of a wide variety of crops. The Fertile Triangle in the old Soviet Union is quite different. Although the region is larger than the one in North America, agricultural productivity is much lower. A large part of the explanation lies in the relationship between the temperature and precipitation zones. As in North America, temperature decreases from south to north. But unlike the North American pattern, precipitation also changes from north to south with the higher precipitation occurring in the south. The result is an agricultural system that is limited to a narrow band where the temperature and precipitation combination is ideal for the crops being grown.

There is another factor at work in this relationship. As we know, temperature and precipitation patterns in the mid-latitudes can be quite variable. There may be years of drought, times when the precipitation comes too early or too late, or there is too much rain or not enough. If this happens within the relatively narrow band of agricultural land in the old Soviet Union, significant losses can occur.

On the other hand, the primary North American agricultural region is displaced over a wider latitudinal band. The likelihood that the entirety of this agricultural region would be adversely affected by adverse temperature and precipitation conditions is virtually nonexistent. There may be climatic problems in part of the region but not in its entirety. The Central Valley in CALIFORNIA is an exceptionally productive agricultural region. This is explained in large part by its north-south alignment and the variety of temperature and precipitation combinations that are available. The Central Valley is the main reason why California is the leading state in value and variety of agricultural products produced.

Climates can change over time. There is geological evidence of these kinds of changes. It is true as well that human activity can bring about climatic change. A case in point is the demise of the tropical rainforest. The moisture that comes from the vast forests through the process of evapotranspiration rises aloft and is transferred north and south of the equator to the mid-

latitude regions. With the loss of moisture from the rainforest, there is the possibility of climatic change in the region receiving the moisture. Finally, continued melting of the pack ice on the Arctic Ocean and the great ice sheets covering Antarctica have already increased the mean temperature of the Earth a small amount. In time, considerable changes in climate could occur, not to mention the possible flooding of populated places worldwide as ocean levels rise.

## climate classification

CLIMATE IS an average or aggregate of daily weather conditions over a period of years. Latitude, distance from oceans, atmospheric and oceanic circulation pattern, elevation, and local geographical features control the climate of a place. The controls of climate result in a plethora of interrelated elements of climate, ranging from temperature, pressure, wind, humidity, clouds, precipitation, ocean currents, and so on.

Climate classifications are orderly arrangements of data dealing with climatic controls and elements. The purpose of such schemes is to identify climate types and subtypes. Maps and graphs display the climates (for example, wet tropical climates). The classifications typically identify climate regions and subregions that cover broad areas that are subcontinental in size.

The display of climate regions on maps helps us understand the location of other environmental features that climate influences. Such climate-related features include water, vegetation, soils, landforms, and wildlife. They also help us understand the influence of climate on distributions of things important to humans, such as agriculture, tourism, living comfort, and

climate-related natural hazards. According to John E. Oliver (1973), there are two approaches to classifying climates—empirical and genetic.

The empirical approach to climate classification uses observed effects of climate (climatic elements). Its primary purpose is to identify the spatial distributions of different climates. The classifications typically use statistics for temperature and precipitation, as weather stations invariably have data on these elements. However, all climatic elements are inherently significant for one purpose or another.

The Köppen classification system is the most famous empirical classification. Originally devised by Vladimir Köppen and published in 1918, the scheme sought to identify vegetation patterns.

Köppen developed statistical parameters using temperature and precipitation data in order to classify climate. He also used vegetation, a natural climatic indicator, as a climate proxy, if temperature and precipitation data were unavailable. A system of letters identifies each climate type; for example, Cfa indicates a humid subtropical climate with a mild winter (C), year-round precipitation (f), and hot summer (a). The Köppen system has undergone various modifications since its inception, but it is arguably the most widely used system for mapping climatic regions on a continental and global scale.

C.W. Thornthwaite devised a rival classification system in 1948. The system focuses on moisture availability and climates. The Thornthwaite scheme is not as highly regarded as the Köppen scheme for its mapping of climates, but it is widely accepted for its practical application to monthly water budget analyses.

Whereas the empirical approach concerns where climates are, the genetic approach seeks to explain why climates are where they are. Thus, genetic classifications use causes rather than effects to delineate climate regions. They focus on dynamic controls of climates (processes that govern exchanges of energy and mass between Earth's surface and the atmosphere). The genetic approach is more theoretical than concrete, as cause and effect is difficult to prove in the complex Earth-atmosphere system.

Geographers developed the genetic approach by focusing on air masses as the main controls of climates. Based in part on the work of Arthur N. Strahler in 1951, John J. Hidore formulated one of the best-known dynamic climate models in 1969. Using seasonal patterns of radiant energy and precipitation, Hidore refined Strahler's earlier grouping of air mass climates into tropical, temperature, and polar types.

The model includes nine climates, three climates in each of the three major groupings. There are also four types of air masses (maritime tropical, continental tropical, maritime polar, and continental polar). The frequency (measured in number of months in the year) and seasonality of air masses in a region determines the region's climate. A world climate map by Strahler and Strahler (2005) has the same tripartite major grouping, but it includes fourteen climates with six possible subtypes.

Climate classification arose from a need to empirically define climates and their boundaries and to explain climate distributions. By the mid-twentieth century, geographers had developed several successful classifications. The schemes used relatively simple statistics, maps, and graphs. In contrast to a growing sophistication in climate science as a whole, climate classification today more often than not relies on these early schemes or revisions of them.

## coastal zone

THE COASTAL ZONE is where nature breathes its essence into poets and painters. Ancient Greeks believed it was where Neptune's energy encounters land. People living in the UNITED STATES call this transition between land and sea the shore, coast, or beach. Robert Gabler et al., define the coastal zone as "the dynamic region on land as well as areas currently submerged under water, through which the shoreline boundary fluctuates."

The seaward margin of the coastal zone is where the motion of approaching waves touches the seafloor. The landward boundary is the highest elevation on the land affected by storm waves. The width varies between a few meters and hundreds of meters. The surface varies from sandy to rocky. The rhythmic rise and

fall of the tide causes the shoreline to fluctuate within the zone.

The coastal zone's appearance depends, in part, on its sediment budget, or the balance between sediment inputs and outputs. The budget involves mostly sand. Waves determine the balance. As waves crash (break) on shore, the turbulent surf and swash (the sheet of water that rushes up the beach) supplies inputs of sand. The undertow, which is water coaxed back into the ocean by gravity, determines sand outputs. A longshore current, which travels parallel to the shoreline and within the zone, transports sand to and from the breaking waves. Longshore currents distribute sediment that rivers discharge into the ocean. Tidal currents help distribute the sediment to sedate areas where waves are weaker and longshore currents do not exist, such as in coves, bays, and estuaries.

Shorelines whose sand inputs exceed outputs have surplus budgets and are of the depositional type. Depositional shorelines in general have large beaches. A beach has two parts: 1) a beach face, which dips gently below the water's edge; and 2) a berm, which is a flat area just behind the beach face. Broad beaches typically have sand dunes on their landward edges. Wind blowing from the sea crosses over the beach, picks up dry sand particles, and transports them to the dunes. Under the right conditions (no storms, dry weather, strong onshore winds, and ample supply of dry sand), dunes grow beyond the landward limit of the coastal zone.

The spit, barrier island, and DELTA are also depositional features of coastal zones. A spit is an offshore ridge of sand that stands above water and runs parallel to a shoreline, but at some point, the spit connects to the shore. A longshore current delivers sand to the spit, allowing it to grow parallel to the shore. The unattached end of the spit sometimes curves shoreward but leaves a narrow opening between itself and the shoreline. A barrier island also runs parallel to the shoreline. It is usually a product of spit segmentation brought about by storm waves.

The semi-enclosed water body (estuary) on the landward sides of spits and barrier islands escapes the brunt of the ocean's wave energy. Weak waves and tidal currents build up mudflats around the quiet estuary's edges. Salt marshes and mangrove swamps thrive on the mudflats. A delta forms at the mouth of a river when the river carries more sediment than longshore currents can redistribute to other parts of the shore.

Depositional shorelines are not without erosion problems. The U.S. southeastern Atlantic Coast and

Gulf Coast are examples. Severe storms cause sand deficits locally that take years, even decades, to replace. Moreover, the region's slow tectonic subsidence causes gradual erosion. A rise in sea level from human-induced global warming also plays an important role, as do the design and placement of human structures such as jetties, groins, and seawalls.

Shorelines whose sand inputs are less than sand outputs have negative budgets and are of the erosional type. The hardness of rock usually determines the shape of an eroding coastline. Pounding waves hack wall-like sea cliffs into the land. Areas that are more resistant to erosion become cliff-edged headlands (sections of land that jut into the sea). Waves focus their rage on the headlands. They carve into their faces sea caves, sea arches, and sea stacks (small rocky islands). Small bays separate the headlands. Waves are weaker there and leave behind narrow, curving strips of sandy beaches. Over time, the unrelenting waves cut into the land to create rocky submarine benches (flat areas). Many erosional shorelines occur where tectonic uplift is occurring. The U.S. West Coast is an example of such a shoreline.

The ever changing, high-energy beach is inhospitable to most life forms. Ubiquitous shorebirds scurry across the sloping beach face, probing for tiny worms, crustaceans (beach hoppers and sand crabs), and mollusks.

Life is more prolific elsewhere in the coastal zone. Rocky edges and bottoms are havens for lobsters, oysters, corals, periwinkles, mussels, barnacles, starfish, and sea anemones. The protected estuary and its fringing mudflats are habitats for an even longer list of species. The mudflats harbor salt-tolerant grasses, fiddler crabs, and tube worms. The nutrient-rich estuary is a refuge for juvenile and adult fishes, crabs, clams, and oysters. Large numbers of birds, both year-round residents and migratory, frequent the entire coastal zone.

## Cocos Islands

THE COCOS (or Keeling) Islands are a dependency of AUSTRALIA located in the INDIAN OCEAN, about 1,675 mi (2,700 km) northwest of Perth, and 620 mi (1,000 km) southwest of JAVA, INDONESIA. Unlike the volcanic peak of their closest neighbor, CHRISTMAS ISLAND, 560 mi (900 km) to the northeast, the Cocos Islands consist of two flat coral atolls, roughly 15.5 mi (25 km) apart. The islands were long owned privately but are today a holiday resort for Australians attracted to its beaches and abundant wildlife.

The two atolls are the tops of the Cocos Rise, a volcanic ridge rising 5,000 ft (1,500 m) from the ocean floor. Reefs started forming here only about 1,800 years ago, and today form a lagoon around the main atoll (South Keeling), covering 43 square mi (110 square km), with over 32 mi (52 km) of reef enclosing 26 small islets. The largest of these are West Island (Pulo Panjang), South Island (Pulo Atlas), Home Island, Direction Island, and Horsburgh Island (Pulo Luar). The smaller atoll is composed of only one island, North Keeling, which is only 1.2 mi (2 km) long and about 1,320 ft (400 m) wide. This atoll is entirely covered by the Pulu Keeling National Park, an important breeding ground for seabirds like the red-footed booby and for green turtles. It is the only island in the Indian Ocean free from natural predators (snakes, weasels, dogs, etc.), and is thus protected as a unique natural habitat. The park, created by the Australian government in 1995, also includes the reef up to .9 mi (1.5 km) around the atoll, known for its 99 species of coral and endless mollusks, crustaceans, and tropical fish.

The islands' two names have both been used since the 17th century. The name *Cocos* appears on mariners' charts at the same time as the sighting in 1609 by Captain William Keeling. The first settlement wasn't built until 1826, when officials of the East India Company brought Malays from SUMATRA and Java to grow cereals, vegetables, and coconuts (for oil and copra) to supply the company's ships. The chief administrator was John Clunies-Ross, and although Great Britain formally annexed the islands in 1857, Queen Victoria granted full rights over the islands to the family of Clunies-Ross in 1886. Sovereignty was transferred to Australia in 1955, but the "kingdom" of the Clunies-Ross family was not finally bought out by the Australian government until 1978 (for 6.25 million Australian dollars) and transferred to the local Cocos Island Council (made up mostly of Malays).

The Cocos islanders then voted to become part of Australia in 1984, giving them citizenship and access to social services. The Cocos Malays are a unique group, cut off from their culture for eight generations, yet remaining strongly attached to their Islamic faith and traditions. Most of them live on Home Island, whereas most Australian government workers reside on West Island. There are no industries, except a small coconut crop, so the island suffers from high unemployment. Tourism is small, though there are plans to open a large resort.

## Colombia

**Map Page** 1139 **Area** 439,735 square mi (1,138,910 square km) **Population** 42,310,774 **Capital** Bogotá **Highest Point** 18,947 ft (5,775 m) **Lowest Point** 0 m **GDP per capita** \$6,300 **Primary Natural Resources** petroleum, natural gas, coal, iron ore.

**COLOMBIA IS** A country located in northwestern South America. Named for Christopher Columbus, it is the only South American country to have coastline on both the CARIBBEAN SEA and the PACIFIC OCEAN. The fifth-largest country in South America, Colombia is a nation of great geographic contrasts. From the 16th through 19th centuries, Colombia was a Spanish colony. In the early 1800s, the country gained its independence as part of Gran Colombia, consisting of modern-day Colombia, VENEZUELA, ECUADOR, and PANAMA. By 1830, Venezuela and Ecuador had separated from Colombia. In 1903, Panama also broke away from Colombia.

The Colombian ANDES consists of three ranges, or cordilleras. The Cordillera Occidental, Cordillera Central, and Cordillera Oriental branch off from each other just north of Colombia's border with Ecuador

and run parallel to the north and northwest. While the Andes in Colombia are not as high as in some other South American countries, they have still traditionally posed a barrier to effective communication in the country. At the same time, they have provided Colombia with natural resources. The Cordillera Oriental is a major source of emeralds, allowing Colombia to become the world's leading producer of the precious stone. Colombia is the world's second leading producer of coffee; most is grown in the Andean highlands at altitudes of approximately 3,000 ft (914 m) to 6,000 ft (1,828 m).

The Andean highlands are the most densely populated region of Colombia. During the 19th and 20th centuries, between 60 and 70 percent of the country's population lived in the 15 percent of the territory located above 3,330 ft (1,006 m). Historically, the Andes have been the center of political and economic power in the country. Before the arrival of Europeans, Native American settlements concentrated in the Andes. Most notable were the Chibchas, a sedentary group who lived near modern-day Bogotá. This region also attracted early Spanish colonists in the 1500s because of its mineral resources such as gold, a more pleasant climate than the tropical lowlands, and the potential labor force of the Native Americans.

In 1538, the Spanish founded the city of Bogotá in the Cundinamarca basin because of the fertile soil and temperate climate. As the capital of Colombia, Bogotá became and continues to be the political, cultural, and artistic center of Colombia. By the early 21st century, the city had nearly 7 million inhabitants. Other major cities in the highlands include Medellín and Cali. Located in the Antioquia region, Medellín prospered in the 19th century from the coffee industry. Residents invested much of the coffee profits in factories, making the city into Colombia's industrial, banking, and commercial center. Cali can be found in the Cauca Valley, a rich agricultural area. At the end of the 20th century, both Medellín and Cali served as centers for the illegal drug trade.

Two major river valleys play important roles in the Colombian highlands. The Cauca Valley is a narrow rift valley through which the Cauca River flows. The Magdalena River Valley is navigable for 600 mi (965 km) from the Caribbean coast. Until well into the 20th century, the Magdalena River was highland Colombia's main link with the outside world, as people and goods traveled up and down the river.

However, there were limitations to transportation along the river, as it possessed a difficult entry to its

mouth and numerous rapids. Travelers sometimes needed as long as two months to travel along the tropical and mosquito-infested river. The Magdalena Valley has also been an important source of petroleum for Colombia.

Colombia possesses tropical lowlands along both the Caribbean and Pacific coasts. The Pacific coast is more sparsely populated. The natural conditions along the Pacific coast, such as the heat, heavy rainfall, and dense forests, have traditionally inhibited large settlements. The Pacific coast has a large Afro-Colombian population. Many of the region's inhabitants practice subsistence agriculture. Buenaventura is the main Pacific Port and is connected by rail to Cali.

Three main port cities dominate the Caribbean coast of Colombia. Founded in 1533, Cartagena was the principal Spanish colonial port in northern South America. By the 19th century, Baranquilla and Santa Marta were the country's main ports. The region around Santa Marta also became an important banana producing area. All three Caribbean ports have been important in connecting the outside world to the main population centers of Colombia in the Andes. Historically, communication took place via the Magdalena River.

The southeastern plains and jungles of Colombia comprise over half of the country's territory. However, the region contains just over 1 percent of the population. Located beyond the eastern Andes mountains, the *oriente* covers some 250,000 square mi (647,947 square km), representing about 60 percent of the country's total area. The region is roughly divided into two parts by the Guaviare River. The northern section of the region is known as the *llanos*, which is an area of grasslands used mainly for ranching. The *llanos* in turn are divided into two parts. The *llanos arriba*, or high plains, are closer to the Andes, receive more rainfall, and are used more for agriculture. The *llanos abajo*, or lower plains, receive much less rainfall and are used principally for grazing. The southern section of the *oriente* consists largely of tropical rainforest that reaches into the Amazon jungle. By the late 20th century, the southeastern section of the country had become more important thanks to the discovery of significant oil deposits.

## colonialism

FROM THE ONSET of trade, the merchant traders established colonies in the foreign places where they did business. Those early merchant colonies were not colonialist in the strict sense. The merchants resided in foreign cities by the grace of the city officials. More commonly, colonialists dominated the indigenous peoples. The Greeks and Romans established military posts in the territory they conquered. The Greeks had most of the eastern Mediterranean islands, and the Romans had control of ISTANBUL, TURKEY, and North Africa to Gaul and Britain. The Roman garrisons included women for working in the fields and increasing the population to the point that the post could become a self-sustaining settlement. The English tried the same philosophy in IRELAND and VIRGINIA, with initial failures giving way to eventual success.

Another case of losing some and winning others came late in the first millennium. The Vikings colonized GREENLAND and Newfoundland, but the colonies failed for lack of support from home. The Norsemen, during their heyday when much of Europe was dark and isolated, enjoyed greater success in colonizing France, Sicily, Ireland and England, establishing a permanent presence as Normans.

Colonizing efforts were also part of the Crusades from the 11th to 13th centuries. And the Mongols of Central Asia established an empire in the 13th and 14th centuries that stretched from the URAL MOUNTAINS to RUSSIA. The Mongols were cavalry, as were the Ottomans who established an empire that included North Africa, the MIDDLE EAST, and the Balkans. The OTTOMAN EMPIRE lasted from the 13th into the 20th century. African and American indigenous peoples were also builders of empires—the Fulani and Zulu of Africa and the Inca and Aztec of the Americas.

## DEFINITION

Under colonialism, a state claims the right to rule territory and people outside its boundaries. The purposes for this rule may include a desire to control resources, markets, or labor. Colonies may also serve as an outlet

for home surpluses of population or goods. Colonialists commonly believe that they are superior in some respect to those colonized. Colonialism can be rationalized as fulfillment of an obligation to lift up the lesser peoples, by whatever means. And defenders of colonialism often cite the economic and political, perhaps even social, benefits that the colonized received from the colonizers.

Modernization and democracy are among the greatest benefits advocates of colonization often claimed. Sometimes colonies did flourish. Success stories included SINGAPORE and INDIA. Countering the benefits argument are dependency theorists such as Andre Gunder Frank, who emphasize that colonialism is a process whereby the colonizer takes resources that would otherwise have allowed the colony to develop on its own. Another criticism, represented by postcolonialist Franz Fanon, is that the mere fact of colonialism promotes psychological and moral and political damage to the colonized.

Historical examples of colonialism abound. Generally, the colonizer uses aggressive acts, commonly military in nature, to acquire territory occupied by others. Colonialism may be used interchangeably with imperialism, but there is also a distinction—colonialism assumes political control, while imperialism may include political or economic domination, either of which can be either informal or formal.

Colonial types include colonies of settlement, colonies of exploitation, and contested colonies. Empires routinely included more than one type. Colonies of settlement included NEW ZEALAND and Virginia, while NIGERIA and JAMAICA were colonies of exploitation. Contested colonies included KENYA, and the British Empire also included a sphere of influence in ARGENTINA and a preexisting empire in INDIA. FRANCE's empire included settlement colonies in ALGERIA and Quebec, exploitation colonies in South America and Africa and a preexisting empire in Indochina.

Colonies of settlement were the result of migration, expulsion of indigenous people, and the assimilation of foreign crops and animals as well as a foreign culture. The colonial settlement of British North America was of this type. So was the settlement of AUSTRALIA. In colonies of exploitation, the European presence was small. Generally, the Europeans were administrators or military officials or merchants. They used whatever means necessary, including force, to establish sufficient political control to achieve the benefits they sought, perhaps strategic location against other European powers or economic advantage.

Colonies of exploitation took advantage of the local economy, using local labor to generate export crops under a plantation system. This type of colony prevailed in Asia and Africa. In the Caribbean and parts of South America, exploitation of the indigenous peoples was so harsh that the labor force literally died away. In these cases, the colonialists resorted to importing plantation labor from other regions where they had some semblance of a colonial presence. The use of African slaves on European-run plantations in Jamaica and the BAHAMAS is an example. A similar approach is the use of convict labor in the French and English penal colonies.

Contested settlement colonies were the ones in which European settlement was pronounced but not sufficient to exclude locals. The Europeans set up their own governments and societies in the midst of the co-existing society. European whites dominated an indigenous population that actually flourished because it remained the basis for economic survival and growth. Eventually the indigenous populations ousted the colonials. This process occurred in Algeria and Rhodesia. The example of India also applies.

At its peak in 1939, European colonialism spanned 20.3 million square mi (52 million square km) with a population of 629 million. The five colonial powers—Great Britain, France, BELGIUM, the NETHERLANDS, and GERMANY (by 1939 noncolonial, but its possessions were mandates and protectorates of the others)—had a combined home population of 172 million people in a space of 1.4 million square km (541,000 square mi).

Economies of the settlements and exploitive colonies were different (in this context the contested settlement colonies were handled similarly to the exploitive colonies). Settlements initially produced raw materials such as wool, gold, agricultural products, ships' stores—their primary markets were the home countries.

As the colonies grew and matured, they came to resemble the European nations economically, with diversified agriculture and manufactures. These colonies acquired self-rule early, which allowed them to use protective tariffs to nurture infant industries. Protection allowed high wages and standards of living. In colonies of exploitation, the home country's influence and control lasted longer.

The colonies remained underdeveloped, often even after independence. Their economies had two sectors—export and subsistence. Exports included sugar, rubber, gold, tin, and other raw products. Capital investment in these colonies was in exports. Another sector was

that of the small native middle class and semiskilled or unskilled labor.

This was the traditional economy, with a low and lowering standard of living as colonial resources left the country via railroads and other infrastructure intended to expedite exports rather than intercolonial commerce and communication. This sector had to make up the social costs of the export sector, characterized by low wages and few benefits.

The squeeze intensified over time as subsistence economy populations grew and the export economy took increasing amounts of wealth for the home country. The postcolonial situation in these colonies was one of dependence on the former colonizer, continued investment in the export sector, and lagging economic development beyond the subsistence level.

### MERCANTILE ERA

A major period of European colonialism occurred from 1492 to 1776. During this time Europeans spread through the rest of the world. PORTUGAL, SPAIN, Holland, France, and England competed in Africa, the Americas, and Asia. Each sought to establish mercantile trade arrangements at the expense of the others. The style was exploitive as each subordinated the indigenous population and established a presence that included military, traders, and plantation managers.

For Spain, the goal was extraction and export of America's gold. The English sought to intercept the gold shipments through piracy. The Dutch specialized in banking and other commercial services. Gold was but the first raw material—where it was unavailable, colonialists exploited whatever resource they found—sugar, tobacco, furs. And they settled as necessary to control their possessions and the transfer of colonial material to Europe. With the INDUSTRIAL REVOLUTION, they also used the colonies as suppliers of raw material and as outlets for their finished goods.

Commonly during the first imperial era, the Europeans found themselves confronted by stronger forces. They had small numbers and only limited technological superiority. They sometimes failed, as in the early efforts in the Americas. Success came when they enlisted indigenous allies—in MEXICO, or Virginia, or CANADA. When the natives resisted in force—in Africa and Asia early on—the conquest was more tenuous. Effective use of the divide-and-conquer technique and a slight technological superiority allowed Spanish conquest in Mexico, and the introduction of European diseases helped the process considerably. Once in power, the Spanish began establishing the extractive export

economy. In Asia, conquest was a matter of Europeans sitting on the coasts as merchants, adapting to local custom, politics, and trading patterns, slowly moving inland as indigenous resistance weakened. Dependence never became dominance, though, because the Europeans lacked numerical or technological superiority.

When possible, the European governments encouraged migration. The French failed to achieve a large enough presence in North America and eventually lost an empire. The English established colonies that grew with natural increase and immigration, taking more land in a slow and methodical conquest of “empty” lands.

The increased European population created a larger export of raw materials, a greater demand for finished goods, and a larger fleet—all within a system that was purely European to European—no local elites to pander to. The only aliens were the slaves imported to make the agricultural economy flourish after Europeans balked at the harshness of the indenture system. The system was unshakable and highly profitable until the American Revolution.

Overall, though, the mercantile effort was a time of harsh rivalry that slowly drained the weaker competitors as they lost markets and gold and the ability to compete against the British system. Portugal, Spain, Holland—all faded as their exploitive empires weakened in the face of England's settlements. Even though France lasted through four colonial wars, it too failed from lack of adequate population to control its territories and feed wealth to the home country. England made political mistakes after the French wars, and the result of its attempt to extract more from the American colonies, now close to mature and certainly not inclined to be exploited, was the loss of the jewel of its empire—the UNITED STATES. Also, the sugar islands became less profitable as the sugar beet became an alternative to slave-harvested cane. Empires went out of fashion for more than a century.

During the hiatus there was sporadic colonial activity, with the British establishing outposts in the Cape Colony (1815), Hong Kong (1842), and New Zealand (1840), while the French entered Algiers and attempted an empire in Mexico. But the rivalry was weak during this period of free-trade imperialism abroad and protection at home.

With European markets closed, Britain especially sought overseas markets. And as the dominant economy in the world, Britain preferred free trade wherever possible. This imperialism was by trade agreement rather than by treaty of surrender (the tool of choice

when occupation was desired, as in the U.S. Native American wars).

### THE FINAL RACE FOR EMPIRE

In the mid-19th century, the race for colonies revived. Rather than entering a great unknown as had the first colonialists, the 19th-century venturers knew what they were looking for and had a good idea of what they would find. And the world map showed that there were only limited areas left to colonize for national prestige and geopolitical influence and maybe the chance to spread the Christian gospel. Markets were the target, not living space.

Triggering factors were the economic depression of 1873, which raised specters of mass unemployment, the Franco-Prussian War of 1870, which revived nationalism, and the reports from Africa of Dr. David Livingstone (1813–73) that encouraged the reformers, Christianizers, and humanitarians.

Russia entered Persia. Austria-Hungary took a bit of the Balkans. ITALY acquired a hold in North Africa. Germany moved toward Baghdad (present-day Iraq) and took a bit of southwest Africa. Britain expanded from the Cape in SOUTH AFRICA to Cairo, EGYPT, took the Suez Canal, and grew its settlements in Canada. Even the United States jumped into the race, taking former Spanish possessions after the war of 1898 and inserting its presence into Canada and Mexico.

This time, the technological advantage was all with the outsiders—railroad tracks and steam engines and the telegraph—as well as vastly more sophisticated weapons and medicines, such as quinine, which allowed Europeans in malarial regions they could not have entered in the first phase. As before, the initial approach was divide and conquer, establish plantations and subordinate the locals, and extract and exploit to fuel the industries at home and increase the national wealth and power.

In Africa, the Europeans failed to recognize that the region was not as primitive as they thought. Trade routes ranged across the SAHARA DESERT north and west. Eastern Africans traded from MOZAMBIQUE to SOMALIA. Inland empires such as Mwene Matapa and Great ZIMBABWE were in the trade network too. With trade came cultural and social interchange. The European intrusion of the first colonialism weakened the fringes of the network, but the 19th-century inroads destroyed the whole thing, to the core of the continent. The British entered Africa with a touch of guilt about their slave-trading history and more than a touch of desire for African products such as groundnuts and

palm oil. To get raw materials for oiling machines and making margarine and soap, the British co-opted local political leaders. Their main interests in the continent were at Suez and South Africa.

With the Suez Canal open, India became 6,000 mi or 9,656 km closer to Britain. When the British bought out the Khedive of Egypt's French canal stock, they had control of the route to India. In South Africa, the attraction was diamonds. After discovery of the Kimberley field in 1870, the British annexed it in 1871. In 1877, they took the Transvaal, leading to a Boer uprising and a British backing off—until the discovery of Transvaal gold. Cecil Rhodes (1853–1902) tried to overthrow the Boers in 1895, and the British fought a second Boer War from 1899 to 1902. Having won South Africa, the British granted home rule in 1906, forcing the colony to take care of financial and moral issues raised by the conquest.

But the discoveries of diamonds and gold mattered more than just to the Boers and British. Europeans wanted a share of the non-European world, no matter its value, just in case. If nothing else, it was a matter of national pride—and having a possession meant that a European rival could not get it. The competition was so fierce that the Europeans met at Berlin in 1884–85 to divide Africa. They agreed no nation would try to take another's territory. By 1914, only LIBERIA and ETHIOPIA were without European control. Elsewhere, peanut, rubber, cocoa, and palm oil plantations appeared, as did gold and diamond mines in South Africa and copper and tin mines in the Congo.

Europeans unseated difficult indigenes but allowed great leeway in matters such as keeping slaves, to those who guaranteed stable labor and good output for export to Europe. The result was a new exploitive economy, and an alteration of internal social and economic relations as the subsistence economy replaced the traditional pan-African one.

### THE END OF COLONIALISM

By the end of the 19th century, the Ottoman Empire was crumbling, but it had assets that the others wanted. Russia wanted access to the Mediterranean via the BLACK SEA. Egypt broke away and became a cotton exporter as well as home to the Suez Canal—and eventually a subset of the British Empire. Persia had oil; Britain and Russia wanted oil. Britain and Russia split Persia at the turn of the century.

Britain had been in India (or at least the British East India Company had been) since the mercantile era. As the indigenous Mughal Empire faded in the

early 18th century, the company took territory after territory. Britain forced enactment of a law requiring India to supply coffee, tea, indigo, cotton, and plantation crops at the expense of internal consumption crops. And Indians were prohibited by law from developing manufactures. The company built railways to the coast, making exports easier.

On the other hand, the British did give India a decent infrastructure—dams, roads, communications, educational system, sanitation—and Indians did show improvements in health and literacy. The lack of adequate agriculture for home consumption did increase the risk of famine and death, and British paternalism weakened Indian culture and exacerbated racial tensions and nationalism. The company lost its franchise in the 19th century, and Britain lost India in the 20th.

The pattern was the same in Southeast Asia, the pathway to the Chinese market as well as a natural area for plantations producing rubber, cocoa, coffee, and sugar. Colonialists progressed from trading post to negotiations with local rulers to control of the local economy to shifting from internal to external crops to increased investment that required a military presence to ensure stability. The Dutch took over INDONESIA's economy and government. Britain acquired MALAYSIA, Singapore, and Burma/MYANMAR.

Frequently, the British used the skills and networks of the overseas Chinese merchants instead of sending Englishmen. Aside from ensuring profitability, this tactic also diverted indigenous hostility away from the British and onto the Chinese. French Indochina was rich with rice plantations. In the area, Siam/THAILAND managed to dodge the colonialists. Colonialism brought schools, sanitation, better health, and outsiders to manage and sometimes to work in the mines and on the plantations. The cultural mix was unstable, changing from the traditional one. And the economic balance was in favor of Europe.

The carving up of China into spheres of influence was a classic case of exploitation without obligation: the open door. China didn't want what Europeans had to offer. But Europeans wanted Chinese tea and porcelain. When the Chinese tried to eradicate their opium trade, the British went to war to preserve the right of free trade in opium. That war (1839–42) ended in the first concessions and the opening of China to European and American exploitation. The end came at the turn of the century with spheres of influence under the open door.

Matthew C. Perry opened JAPAN in 1854 as the United States sought links to Asia for trade. The mo-

mentum halted during the American Civil War, but post-Reconstruction industrialization spurred demands for raw materials and markets and some stability for an unstable economy. Military and missionary impulses were strong too, as was the "white man's burden" to remake the world in the Euro-American image. And national ego was on the line. Imperialist successes came with the purchase of ALASKA, the annexation of the Midway Islands, and finally Samoa (a naval base on Pago Pago in 1878; formal partition in 1899) and HAWAII (annexed 1898), both on the trade routes—Samoa on the route to Australia, Hawaii to the broad Asian market. And the PHILIPPINES, insignificant for trade, but a stepping stone to the Asian markets, was also acquired. Other stepping stones to Asia included Guam, Wake, and Johnston Atoll. When China opened, the United States was ready.

There was also the matter of Latin America, another victim of free trade with European and American businesses backed by government pressure forcing their way into a peasant economy, working with local elites to make market economies. Eventually, German and American control came to indigenous industries. U.S. interest included the mid-1850s filibusters of William Walker, the repeated talk about annexing CUBA and the attempts to buy it. After Spain lost the war of 1898, the United States kept bases and controlled internal affairs, foreign policy, and the economy until 1934 under the Platt Amendment; Cuba was a de facto protectorate.

Eventually, prior to nationalization in Mexico, American interests controlled 70 percent of Mexico's oil and 80 percent of its railroads. In Canada, American companies were strong in the automobile industry as well as electrical and forest products. This was the precursor to the post-World War II economic colonialism.

Japan modeled itself on the colonialist model instead of letting itself become colonized. It became militarily strong and modern, industrialized, and adapted what worked from Western ideas, and discarded the rest. Nationalist and disciplined, Japan became a regional imperialist after it defeated Russia. The Japanese carved out their section of China and expanded the Greater East Asia Co-Prosperity Sphere until it clashed with U.S. aspirations in Asia.

## COLONIAL CONCLUSION

The colonial experience brought progress to the colonized, but it also brought greater prosperity to the colonizers. At the beginning of the first colonial era,

wealth was distributed more equitably than it was at the end of the second. The disparities continued to grow. Global empires covering 8.75 million square mi (22.6 million square km) did not last. After World War II, the colonial Europeans were discredited and debilitated by the costs of the war. Their empires crumbled as country after country in Africa and Asia won or received independence. Some emerged more easily than others; all faced major difficulties, being mostly economically backward with inadequate experience in determining their own futures. They may have been politically free, but they remained export-oriented economies with subsistence populations with marginal skills and education and no serious prospects of equal competition in a free trade world. The new buzzword was neocolonialism.

Neocolonialism is a product of the postwar economic arrangements made by the European winners at the Bretton Woods economic conference. Critics point to the World Bank and World Trade Organization, created at the conference, as the tools of neocolonialists, as is the American business and popular entertainment component.

Neo-colonialism entails simple influence over a sector of an undeveloped country by a more developed one. From imposition of English as the language of commerce everywhere, to imposing Coca-Cola and Disney and McDonald's as popular culture, to requiring that developing economies mimic the mature economies of the West or allowing multinational corporations access to compete with nascent indigenous ones—to the critics it all seems to be a matter of the Eurocentric world gaining advantage at the expense of the weaker partner in the third world, culturally or economically. It is the old, old colonialism, just under a new guise.

## Colorado

COLORADO IS ONE of the Rocky Mountain states located in the west-central part of the UNITED STATES. All of Colorado is more than 3,300 ft (1,000 m) above sea level. With an average elevation of 6,800 ft (2,070 m), Colorado is the highest of all the states. *Colorado* is a Spanish word meaning “reddish colored” and was the name early Spanish explorers gave to the Colorado River when they first explored the region in the late 1500s. The state is bordered by WYOMING and NEBRASKA in the north, KANSAS and NEBRASKA in the east, NEW MEXICO and OKLAHOMA in the south, and UTAH in the west.

In the southwestern corner of the state, four state boundaries come together (New Mexico, ARIZONA, Utah, and Colorado) forming what is known as the Four Corners. Colorado, like Wyoming, is rectangular in shape with a combined area of 104,100 square mi (269,837 square km), making it the eighth largest of the 50 states. Colorado has 4,301,261 residents, ranking 24th among the 50 states. With only 41 persons per square mi (106 per square km), the state ranks 37th in population density. The state's 10 largest towns, all located in a 175-mi- (282-km-) long corridor along the Front Range from Fort Collins in the north to Pueblo in the south, account for 45 percent of the total population. Denver is the state's largest city as well as the capital.

The ROCKY MOUNTAINS, running from north to south through the middle two-fifths of the state, are the most dominant physical feature. In contrast, the eastern two-fifths of the state is part of the Great Plains, a relatively flat, treeless plain that extends from the mountains eastward to the Nebraska and Kansas state borders. To the west of the Rockies, the Colorado Plateau covers the remaining one-fifth of the land. In addition, Colorado includes small sections of two other natural regions, the Wyoming, or Green River, Basin and the Middle Rocky Mountains, both of which

lie in the extreme northwestern part of the state. Colorado also straddles the Continental Divide, which separates rivers flowing to the PACIFIC OCEAN and the Gulf of Mexico. Lands west of the divide whose waters flow to the Pacific are referred to as the Western Slope, while those to the east with waters flowing to the ATLANTIC are referred to as the Eastern Slope.

Five mountain ranges make up the Colorado Rocky Mountains: the Front Range, the Sangre de Cristo Mountains, the Park Range, the Sawatch Range, and the San Juan Mountains. The mountains are not part of a single highland area but are divided into two roughly parallel groups. The eastern mountain belt includes the Laramie Mountains, the Front Range, and part of the Sangre de Cristo Mountains. The highest peaks of these eastern ranges are Blanca Peak, Longs Peak, and Mount Evans, all of which are more than 14,250 ft (4,340 m) high. Pikes Peak, the state's most famous landmark at the southern end of the Front Range, rises to 14,110 ft (4,301 m). The western belt of high mountains includes the Park Range, the Sawatch Range, and the San Juan Mountains. The Sawatch Range contains Mount Elbert, the state's highest peak at 14,433 ft (4,399 m). The Sawatch Range and the San Juan Mountains combined contain 27 of the state's mountains over 14,000 ft (4,250 m).

Several broad, high-altitude valleys and mountain basins called parks separate the mountain belts from each other. The parks and valleys between the two mountain belts of the southern Rockies are broad, relatively flat, grass-covered areas. The principal ones are, from north to south, North Park, Middle Park, South Park, and the San Luis Valley.

The Great Plains region covering the eastern two-fifths of the state is a broad expanse of flat or rolling prairies that rise from about 4,000 ft (1,200 m) above sea level along the Kansas state line to approximately 7,000 ft (2,100 m) above sea level at the foot of the Rocky Mountains. The Great Plains region is not uniform throughout the state and is often divided into the High Plains, the Colorado Piedmont, and the Raton section. The High Plains are mostly level lands that extend along the eastern border with Kansas. The Colorado Piedmont, which lies to the west of the High Plains, is more varied in relief with low ridges, steep bluffs, flat-topped mesas, and conical hills referred to locally as called tepee buttes. The Raton section to the south of the Piedmont is more rugged, with numerous mesas and buttes of volcanic origin and narrow, rocky canyons that often appear out of nowhere. The plains region is primarily a dryland farming area used for

growing wheat and grazing cattle, although the use of irrigation has allowed an increase in corn and sorghum production in areas where groundwater is sufficient to support pumping.

### COLORADO PLATEAU

The Colorado Plateau occupies the western two-fifths of Colorado. Originally named by explorer John Wesley Powell, the plateau is in fact a huge basin ringed by highlands and filled with dozens of separate plateaus that range from about 5,000 to 11,000 ft (1,500 to 3,400 m) high. As a physiographic "province," the region is geologically and topographically distinct from other parts of the west remaining structurally intact for the past 500 million years or more. Sprawling across southeastern Utah, northern Arizona, northwestern New Mexico, and western Colorado, the Colorado Plateau covers a land area of 130,000 square mi (336,700 square km). Of America's 50 states, only ALASKA, TEXAS, CALIFORNIA, and MONTANA are larger. One of the plateau's unique features in Colorado is the Black Canyon of the Gunnison, a deep gorge cut by the Gunnison River that is deeper than its more famous neighbor, the Grand Canyon, in places.

Colorado's earliest inhabitants were Native Americans who settled in the mesa country more than 2,000 years ago. The first European to enter the region was probably the Spanish conquistador Francisco Vázquez de Coronado in the 16th century, with Spain claiming

*A scenic vista of Colorado State Park, in the Rocky Mountains, typifies Colorado's western region.*

the area in 1706. France also laid claim to the area as part of its Louisiana Territory, although no settlements were established. The United States bought the area north of the Arkansas River and east of the Rocky Mountains as part of the LOUISIANA PURCHASE in 1803.

Early expeditions to the area explored routes opened earlier by the famous mountain men, trappers, and fur traders. While Bent's Fort along the Arkansas River became one of the best-known trading posts in the region, settlement did not begin until the United States acquired the remainder of present-day Colorado from MEXICO in the Treaty of Guadalupe Hidalgo in 1848. It was the discovery of gold at Cherry Creek (present-day Denver) in 1858 that brought large numbers of settlers to Colorado. Interestingly, the area was part of the Kansas Territory at the time. Measures proposing statehood for Colorado were introduced in the U.S. Congress in 1864, although Congress did not pass the bill granting Colorado's statehood until 1876.

The mining booms of the late 1850s spurred Colorado's initial growth. The state's economy broadened when irrigated agriculture developed, and by the late 19th century, livestock raising had become dominant on the eastern plains. Early industrial growth was based on the processing of minerals and agricultural products. In the second half of the 20th century, the industrial and service sectors expanded as did winter resorts and summer recreational opportunities.

Manufacturing is dominated by the processing of local raw materials and by technology-dependent light industries. Leading manufactures include the production of scientific instruments, food processing, and the making of industrial machinery. The brewing of beer is the leading employer among food-processing industries, although the state has a diverse selection of industries preparing and packaging Colorado's farm output. Colorado is the nation's fourth-largest producer of cattle. The sale of livestock and livestock products (mostly cattle and calves) accounted for 72 percent of farm income in 2002. Western Colorado is the leading sheep-raising area in the state. The sheep are raised for both wool and meat, especially spring lambs. Hogs and dairy products contribute significantly to the state's agricultural economy as well.

Wheat is the leading cash crop, raised primarily on the High Plains. Corn is the second most important crop, although most of the corn is fed directly to livestock. In some plains areas, barley, grain sorghum, and oats are also grown, often in rotation with wheat. In addition, many stock farms raise both wheat and cattle. The production of fossil fuels is by far the most

valuable resource extraction, representing four-fifths of the state's mineral output and natural gas the leading individual mineral product. Most of this production takes place in the northwestern part of the state.

CHINA AGRICULTURAL UNIVERSITY

## commercial agriculture

PRIOR TO THE FIRST AGRICULTURAL REVOLUTION, people relied on hunting and gathering to obtain food supplies. The agricultural revolution began as the individuals in the society began to cultivate soil, plant seeds, and use plows and animals to assist with the cultivation of the soil. This change from a hunting and gathering society did not occur in just one place but appeared almost simultaneously around the world. This first phase of the agriculture revolution took place approximately 10,000 to 12,000 years ago.

In the 17th century, a second agricultural revolution began. During this phase agriculture production and distribution increased, individuals became less dependent on growing crops themselves, and they began to move to the cities starting the INDUSTRIAL REVOLUTION. In the years between the first agricultural revolution and the second little changed with the way that agriculture was grown and harvested. It was during the second agriculture revolution that commercial agriculture was developed. This involved a shift from hand labor to machine farming. Between 1860 and 1910, the number of farms in the UNITED STATES tripled, from 2 million to 6 million, while the area farmed more than doubled.

The third revolution began in the 1920s with the development of fertilizers, chemical farming, and the

processing and refining of food. The main characteristics of this agricultural revolution were the blending of primary, secondary, and tertiary activities, intensification of mechanization, and development of biotechnology. One of the main elements influencing the third revolution was the green revolution, which is a process of technological development of agricultural techniques that began in Mexico in 1944 and has since spread throughout the world.

The agricultural revolutions and their main characteristics include:

*First revolution.* Before 10,000 B.C.E. in Europe and Southeast Asia: expansion of seed agriculture and the use of plow and draft animals; development of settlements, farming; population increase.

*Second revolution.* 1700s in western Europe and North America: production of an agricultural surplus and the development of commercial agriculture; closely associated to Industrial Revolution (begins in Britain; later spreads across Europe).

*Third revolution.* 1920s in western Europe and North America: development of agriculture, industry, chemical farming, and inorganic fertilizers (biotechnology); agriculture is related to processing and refining of foods.

Today, about 45 percent of the world's population makes its living through agriculture. The proportion of the population involved in agriculture ranges from about 2 percent in the United States to about 80 percent in some parts of Asia and Africa. Farming in the 20th century has become highly technological in the more developed nations, while less developed nations continue with using growing practices and methods that are similar to those developed after the first agricultural revolution.

## TWO TYPES OF AGRICULTURE

At present, there are two main types of agriculture: subsistence and commercial agriculture. Subsistence agriculture is defined as producing food primarily for local consumption (the farmer's family) and most often occurs in developing nations. Commercial agriculture is the production of crops for sale and is designed to produce crops for widespread distribution (supermarkets), larger markets, and export. It also extends to limited distribution (local produce stands) and any nonfood crops such as cotton and tobacco. It contributes substantially to the gross domestic product of a country.

Commercial agriculture is found in both the developing, developed, and the most the developed nations.

*The advent of corporate farms endangers the viability of the family farmer in developed and underdeveloped nations alike.*

This is now the predominant form of farming in Southeast Asia and throughout the world and includes major fruit plantations in Central America as well as enormous agribusiness wheat farms and facilities in the midwestern United States. In developed countries, farmers are involved in large-scale commercial farming, both rain-fed and under irrigation. In addition, they receive substantial government support aimed at increased domestic production and exports.

Agriculture was brought into the multilateral trade rules at the conclusion of the Uruguay Round and the establishment of the World Trade Organization (WTO) in 1995. Critics say the agreement tends to emphasize commercial as opposed to subsistence farming.

It is believed that a successful transition to a system of high-yielding commercial agriculture will open new opportunities for developing countries by allowing farmers to benefit from advanced technologies and expanded trade opportunities. However, not all farmers

will gain from these changes. Many small-scale subsistence farmers in more remote areas where the new technologies are less suitable may become more vulnerable and increasingly marginalized.

Since the beginning of the 1990s, there has been a considerable increase in the production of commercial cash crops. There has been a dramatic increase in the land planted to grow annual crops—cotton, jute, sugarcane, peanut, soybean, tobacco—as well as crops planted more than once a year: tea, coffee, rubber, peppers, coconut, and fruit crops. The farming of cattle and pigs has also increased.

### TECHNOLOGY

Rapid changes in technology are the characteristic of U.S. agriculture and a major force of contemporary commercial agriculture. Agricultural industrialization is a process in which the role of the farm has moved from the centerpiece of agricultural production into being only one part of the system of production. This also includes storage, processing, distribution, marketing, and selling the food. With agricultural industrialization, the farm becomes only one link in a large chain of food production.

In developing countries, mechanization and technological advances are not widely seen. This can be attributed to small land holdings, scattered plots, and poor rural infrastructure. Low income levels and the availability of cheap household labor also discourage households from either purchasing or renting machinery. Despite a government rhetoric encouraging industrialization and modernization, farm mechanization is hampered by a lack of positive government policies such as finance subsidies, low-interest loans for farm machinery, tax exemptions for the manufacturing of machinery and fuel to operate the farm machinery.

Other trends in commercial agriculture during the 1990s include consumerism, internationalization, environmentalism, policy change, and high technology. Historically, farmer's main objective was to keep up with the food demand generated by a growing population. However, over time, the population not only requires that basic energy requirements are met, but it is demanding better access to a wider variety of nutritious foods. Today's consumers are very concerned about the nutritional characteristics of the food as well as the safety of the food. With the increasing number of both men and women in the labor force, there is an emphasis on developing new products that not only meet the nutritional and the safety requirements but also increase the ease and speed of preparation.

Because of the size of the world market, internationalization is one of the fundamental forces affecting the well-being of U.S. farmers. In the international market many of the crops are characterized by: 1) marketing value-added products; 2) developing more alternative crops and more specialty crops; and 3) finding new ways to deliver those to foreign consumers in the form in which they want to buy. We live in a global market and a global society. This creates tremendous opportunities for the U.S. farmer to draw upon genetic material and new crops from other countries.

The third major trend of the 1990s is increasing concern for the environment. One of the goals is to provide modern agriculture with the best available, most environmentally friendly irrigation, prevention of soil erosion, and pest control.

The change is in the policy of farming or agriculture. There has been a decline in the role of "old-line" subsidy programs for corn, soybeans, wheat, cotton, and rice, programs that used to make up the most important elements of the U.S. agricultural policy. Instead, the new agenda is free trade, environmental conciseness, concern for the welfare of the animals that are farmed, and food safety.

Lastly, in the 1990s, agriculture is becoming an increasingly high-tech industry. There is a tremendous array of powerful tools of modern plant science at our disposal used to improve traditional crops through genetic manipulation and to find alternative means of pest control.

### PROBLEMS

Some problems with commercial farming include overproducing, harvesting fewer varieties of food, and limiting the ability of the small farmer to be able to earn a living.

Overproduction or an oversupply of food because of mass production has had a negative impact on both small and commercial farmers, as it often reduces their incomes. However, government policies often try to control overproduction through different means: paying farmers not to grow cash crops; providing price supports for products that are sold too cheap; and buying surplus production and then storing it, donating it, or destroying it.

With the global spread of commercial agriculture, fewer varieties of food are being planted in shrinking areas of arable land. Varieties of rice, corn, and wheat and new forms of livestock breeding have displaced many local varieties of crops and animal breeds. The United Nations Food and Agricultural Organization

(FAO) has estimated that more than 75 percent of agricultural crop varieties and more than 50 percent of domestic livestock breeds have disappeared over the past century because of modern farming methods. "The spread of modern, commercial agriculture and the introduction of new varieties of crops has been the main cause of the loss of genetic variety," explains an FAO report. When coupled with the rapid spread of commercial agriculture, market barriers, and the privatization of knowledge that has accompanied advances in biotechnology, the patenting of life forms poses a direct threat to the livelihoods of farmers and indigenous communities in developing countries.

In Asia, large resettlement schemes, intensive timber harvesting, and the expansion of commercial agriculture have been important agents of deforestation and forest degradation. The conversion of forest to plantations—both forest plantations and agriculture plantations of rubber and oil palm—has also been carried out on a large scale.

From a commercial perspective, the world hopes for greater security, protecting fragile environments and reforming local farm policies. To achieve this, developed countries must find less trade-distorting ways to support rural incomes and end the practice of subsidizing their exports. Developing countries need to embrace a similar vision of openness and allow imports as well as exports, as nearly half of global food trade, and virtually all of its growth potential, is among developing countries.

Second, the developed world needs to assist and encourage developing countries to build upon their capacity to participate in a global economy and to ensure that the rural farmers gain from globalization. Developed countries have pledged to reduce global hunger dramatically by increasing aid going to rural development and investing in commercial opportunities for developing country entrepreneurs. If these policies are appropriately supported by agricultural trade consortiums, the investment could increase and broaden the gains in a short amount of time instead of decades.

Finally, attitudes toward new technologies, especially agricultural biotechnology, need to be reexamined. New technologies can raise agricultural productivity and human nutrition at an affordable rate. It would be unfortunate if developing countries were denied these tools by trade barriers disguised as safety or marketing rules unsupported by science.

## Comoros

**Map Page** 1116 **Area** 846 square mi (2,170 square km)  
**Population** 632,948 **Capital** Moroni **Highest Point** Le Kartala 7,788 ft (2,360m)  
**Lowest Point** 0 m **GDP per capita** \$720 **Primary Natural Resources** tourism, arable land, agricultural products.

COMOROS IS ONE of the world's poorest, and also most politically unstable countries. Located off the east coast of Africa, at the northern end of the MOZAMBIQUE CHANNEL, the Comoros developed under the mixed cultural influences of the Arab and East African world, plus European colonialism in the 19th century. The island group consists of Njazidja (also known as Grande Comore), the largest, with the capital of Moroni, plus the smaller islands of Mwali (Mohéli) and Nzwani (Anjouan). A fourth island, Mahoré (Mayotte), has retained its administrative links with FRANCE, despite intense local and international pressure. The islands have suffered from nearly 20 coups since independence in 1975, and further disintegration was heralded by proclamations of independence by two other islands, Mwali and Nzwani, in 1997. But a new attempt at compromise, promising a greater degree of local autonomy, was signed in 2001.

The islands of the Comoros are volcanic in origin and of varying ages. The most recently formed, Njazidja, has two major volcanoes, the extinct La Grille in the north (3,300 ft or 1,000 m), and Kartala in the south (7,791 ft or 2,361 m), which last erupted in 1977. Nzwani and Mwali are geologically older, and

have had time to form a richer soil from erosion and weathering. Most of the islands were formerly covered in lush tropical vegetation, and Nzwani and Mahoré have extensive coral reefs; both forests and reefs provide rich habitat for rare and interesting wildlife, such as the Livingstone fruit bat, the world's largest bat, with a wingspan of up to 6.6 ft (2 m), and the coelacanth fish, the "living fossil" with limblike fins, thought to have been extinct for 70 million years until its rediscovery in 1938.

Located on the TRADE ROUTES between the Arab world and East Africa, the islands were named by early Arab geographers *kamar* or *kumr*, meaning "moon." Early immigration from southeast Asia to MADAGASCAR left a small Malayo-Indonesian population, followed by immigrants from the East African coast, then settlements of Arab traders known as the Shirazi from the 15th century. This mixture of Malay, Arab, and African ethnic groups created the unique culture of the Comoros today and continues to manifest itself in strong ties to various states of the INDIAN OCEAN basin.

The Shirazi Arabs set themselves up as rulers and divided the islands into numerous sultanates. For many years they controlled much of the slave trade from east Africa to French plantations in Madagascar, MAURITIUS, and Réunion Island. Internal conflicts led to French occupation, first on Mahoré in 1841, then gradually over the other islands. The last sultan abdicated in 1912, and the islands became a formal part of the French colony of Madagascar until 1946. Internal self-rule was granted in 1961, followed by a referendum in 1974, in which 95 percent of the population voted for independence, but not on Mahoré, where 65 percent voted to remain part of France. This conflict, and the struggle between socialist and conservative Islamic groups, has resulted in the high political instability over the past four decades.

Economically, colonialism wrecked the Comoros, creating a system of near complete dependence on products not suitable for domestic consumption. After slavery was banned in French colonies in 1848, planters turned the islands into exclusive zones for rare tropical products, especially ylang-ylang (used in perfumes and soaps) and vanilla. The Comoros remains the world's largest producer of these two products, but is unable to feed itself and relies heavily on foreign aid, mostly from France, but increasingly from conservative Islamic states in the PERSIAN GULF. Islamic ties are strong, stressed in the official name, the Federal Islamic Republic of the Comoros, and symbolized by the crescent moon (from the name of the country) used in the

country's flag, which also stresses the desire for unity among all of the islands, depicting four stars, rather than three.

## computer mapping

COMPUTER MAPPING IS the general term used to describe the process of developing digital maps from aerial photographs, satellite images, global positioning systems (GPS) records, paper maps, and other archival data sources. GEOGRAPHIC INFORMATION SYSTEMS (GIS) are currently the most common implementation of computer mapping systems. A GIS consists of an organized collection of computer hardware, software and trained personnel designed to capture and manipulate geographically referenced data for generating digital maps. Digital maps have the capacity to store information that is more detailed and allow the map features to link to external databases. One application of a GIS-based mapping system is automated mapping (AM), where digital inventory maps of facilities such as telephone and utility lines are linked to database information to aid in facilities management (FM). The overlaid system is known as AM/FM.

At the core of the computer mapping process is data capture, conversion, and verification. The availability of many forms of existing digital (such as satellite images and aerial photographs) and analogue (such as paper maps and statistical tables) data demands a level of flexibility to deal with these different formats during the mapping project. The general stages involved in computer mapping are to obtain the digital data, digitize any relevant analogue data, conduct a ground survey if necessary, align the digital data layers with a common reference system, and develop a continuous surface from the digital maps. The result is a spatial database that can be queried to support planning and decision-making goals.

Satellite images and aerial photographs are the most widely used inputs for many digital mapping projects. The computer-driven process of making the

raw satellite image and aerial photographs useful is termed *image analysis* or *photogrammetry*. These forms of raw data are already digital, and together with their affordable cost and frequency of collection, they provide significant advantages over other data sources. In addition, since the data is already in a digital format, errors based on data conversions are minimized. But in situations where data of high spatial resolution is required, such as for facilities planning using street networks, digitized maps and GPS data are needed to represent local-level map details.

The paper map is also a valuable input source for digital mapping projects. These paper maps are mostly topographic (showing earth features) or thematic (showing specific features), and drawn to a certain scale, and the attributes of features are encoded by colors and symbols. An important characteristic of the map is that geographic features are identified by a common coordinate or reference system. The common reference ensures that identical features are at the same coordinate position in all the digital database layers. This common referencing serves to integrate the various layers of the spatial database.

The process of manually entering data for use in a mapping project involves iterative stages of recording the spatial data, entering the attribute data, verifying the data entries, and linking the spatial and attribute data. For paper maps, a digitizer device, with its flat tablet and a connected cross-haired mouse, is used to trace each of the geographic features manually. At the particular map scale, all the features of interest on the map are encoded as points, lines, or areas, depending on how they are represented on the paper map. The final digital map elements are checked for correctness and may involve tasks such as verifying object shapes or field checks. A unique identification number is used to link the digital map objects to attribute data entered into a database. The discrete map objects consisting of points, lines, and areas are called vector data.

Document scanners are also used to convert analogue to digital data. The scanning process generates raster data as the paper map is captured as a two dimensional array of cells. The resolution of the digital data is characterized by the size of the cells. Each cell contains information about the component elements of the paper map. A smaller cell size (greater resolution), determined by the document scanner capabilities, means that any particular object on the map will be defined by more cells.

Issues such as increased computer storage requirements arising from more cells and the desired accuracy

of the digital map are challenges for this stage of the process. The scanned image will inevitably contain imperfections. Each grid cell needs to be encoded with information about the geographic feature it contains. Moreover, the image space must correspond to a map coordinate system. These tasks are accomplished with image analysis procedures that modify the cell attributes. The final digital map elements are checked for correctness and may involve tasks such as verifying object shapes or “ground truthing,” after which the image is ready for integration into existing spatial databases.

Georeferencing is an important part of creating the spatial database. During the georeferencing process, the raw digital data is projected so that the individual map objects are correctly arranged in some specified map coordinate system. The process begins by selecting identifiable objects on the digital map for which the real world (latitude/longitude) coordinates are known. The selected objects must be evenly distributed across the map surface as the georeferencing process uses them as fixed anchors to warp the entire digital map space to fit a selected coordinate system. A common coordinate referencing system ensures that all the map layers can be coupled.

## Congo

**Map Page** 1115 **Area** 132,047 square mi (342,000 square km) **Population** 2,954,258 **Capital** Brazzaville **Highest Point** 2,963 ft (903 m) **Lowest Point** 0 m **GDP per capita** \$900 (2002) **Primary Natural Resources** petroleum, wood, potassium, potash, gold.

THE REPUBLIC OF Congo is located in western Africa and covers an area slightly smaller than MONTANA. It is bordered by GABON to the west, CAMEROON to the north, the Democratic Republic of the CONGO (formerly Zaire) to the east and south, the Angolan Cabinda enclave to the southeast, and the ATLANTIC OCEAN to the east. Congo's border with the Democratic Republic of Congo is the country's only natural boundary, which follows the CONGO and Ubangi rivers. Congo gained its independence from FRANCE on August 16, 1960.

Congo has a tropical climate that is warm and humid with heavy rainfall occurring mainly from March through June. Dense tropical RAINFORESTS start at the equator and cover the northern part of the country. South of the equator, there is a savanna area with diverse wildlife, including antelope, giraffe, cheetah, and crocodile, along with many birds and snakes. Also encountered in the southern part of Congo are central plateaus, fertile valleys, and coastal plain and forested floodplain areas.

In the Congolese valleys are grown the primary subsistence crops of cassava and yams. Export crops, raised on plantations in this area, consist of sugarcane, tobacco, coffee, cacao, palm products, rice, corn, and groundnuts.

### RIVER LIFE

Many of the rivers in Congo play a large part in the economic and commercial life of the Congolese people. There are over 2,300 mi (3,700 km) of navigable rivers in the country. The main river routes are along the Congo and Ubangi rivers. Brazzaville, the capital of Congo, is a large river port along the Congo River. Because of the effectiveness of transportation along the rivers and the vastness of the northern rainforests, the Congolese road system has barely been improved, and today consists only of 7,450 mi (12,000 km) of roads.

The Congolese forests constitute one of the major natural resources in Congo and are the primary agricultural export of Congo. These timbers were the top export of Congo before the discovery of oil in the country and now constitute only 7 percent of export earnings. The majority of these trees are oil palms and *okoume*. Oil was first discovered in Congo in 1957 at Pointe Indienne. Since then, oil has been Congo's largest export, making up 89 percent of the export earnings in 2001. At that time, the Republic of Congo was producing 275,000 barrels of oil per day.

Congo is one of the most urbanized countries of Africa with over 85 percent of its total population liv-

ing in the southwestern part of the country. Brazzaville has the highest population at over 800,000 people, followed by Pointe Noire with 450,000 people. The rest of the Congolese people live mainly in small cities or villages along the railroad connecting Brazzaville, located roughly 310 mi (500 km) inland along the Congo River, to Pointe Noire on the southern Atlantic Ocean. Along this railway lives more than 75 percent of the Congolese population. Even though Congo has a relatively concentrated population in these areas, the overall population density is low because vast areas of swamps and rainforest are uninhabited.

The ethnic diversity in Congo is also great. The Bantu people make up the majority of the population and include four groups. The largest group of the Bantu people is the Kongo, making up about 48 percent of the population. They are mostly farmers or traders, live primarily around Brazzaville, and speak Bantu. The Teke or Bateke, another Bantu-speaking group, make up 17 percent of the population. The remaining Bantu peoples are the Sangha and the M'Bochi. Also present in Congo are the country's first inhabitants, the Pygmies. There are fewer than 100,000 Pygmies in Congo today, and they live mainly in small tribal groups in the forests along the Congo River and in the rainforests north of the equator.

## Congo, Democratic Republic of

**Map Page** 1115 **Area** 905,563 square mi (2,345,410 square km) **Population** 56,625,039 **Capital** Kinshasha **Highest Point** 16,765 ft (5,110 m) **Lowest Point** 0 m **GDP per capita** \$590 **Primary Natural Resources** diamonds, gold, silver, tin, bauxite.

THE DEMOCRATIC Republic of Congo (DRC) is strategically located as the geographic centerpiece of Africa. Smaller in area than only SUDAN and ALGERIA, the DRC is the third-largest country on the African continent and is slightly less than one-fourth the size of the UNITED STATES.

### ECONOMIC DISTRESS

Though possessing tremendous mineral resources, as well as the largest forest reserves and the largest hydroelectric potential in Africa, the DRC remains mired in economic distress owing to a history of exploitation. This exploitation began in 1885 when King Leopold of BELGIUM gained control of the area then known as the Congo Free State and treated the land and its people as his own personal fiefdom. In 1908, it became a colony of Belgium and remained under Belgian control until gaining independence in 1960.

Independence, however, did not bring an end to the troubles facing the DRC. Woefully unprepared for self-determination, the country quickly came under the dictatorial rule of Mobutu Sese-Seko. For the next 35 years, the DRC remained under Mobutu's corrupt and brutal control until a military occupation of Kinshasha ended his one-party rule in 1997. Yet the rewards of deposing Mobutu remained indeterminate, as the country has since been wracked with ethnic strife and civil war involving both internal and external forces. It is this continuing legacy of instability that has mired the Democratic Republic of Congo in a state of poverty.

### RICH RESOURCES

Despite being one of the poorest countries of Africa, the DRC could be one of the continent's richest. The CONGO RIVER basin and its vast resources dominate the country's landscape. Emanating from Lake Mweru in the far southeast, the Congo River crosses the equator twice before reaching the ATLANTIC OCEAN some 2,880 mi (4,630 km) later. Carrying the second largest volume of water in the world, the river could provide substantial hydroelectric power. Heavy annual rainfall averaging along the equator contributes to the river's flow, as well as to the equatorial rainforest covering more than 50 percent of the country.

The forest contains a tremendous variety of flora and fauna, including such rare animals as the gorilla. Further south of the equator, as well as to the highlands of the east, the rainforest gives way to savanna GRASSLANDS where lions, antelope, and giraffes can be found.

The size of the DRC, which offers such resource potential, also serves as a liability. With a predominantly rural population composed of over 200 major ethnic groups speaking more than 700 different languages and dialects, the Democratic Republic of Congo must improve its transportation and communication network. The country's population is clustered between the forest and highlands of the east, and in the strip of land stretching west from to the 25 mi (40 km) strip of coastline along the Atlantic Ocean through the capital of Kinshasha and into East Kasai.

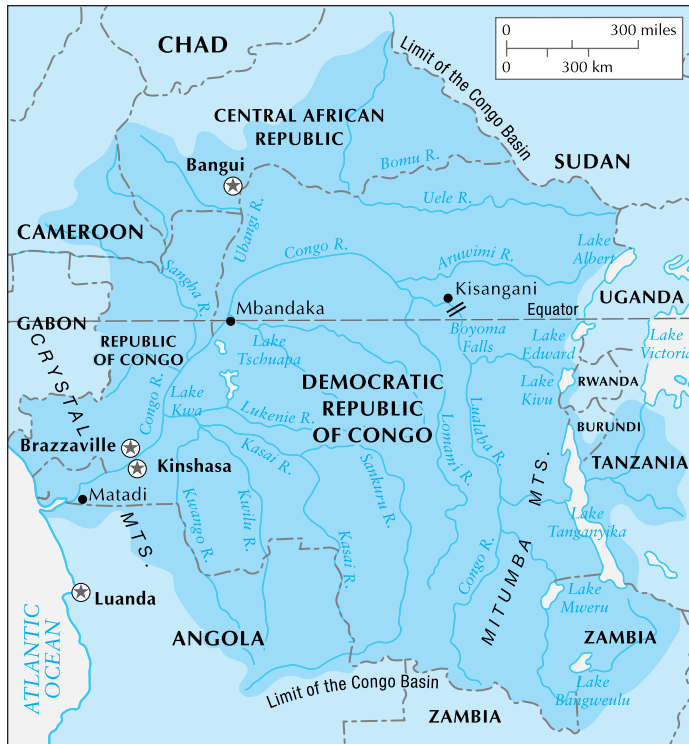

Most of the people are involved in subsistence agriculture and other primary activities, including mining. Cash crops, including coffee, cocoa, and palm oil, are also important, though difficult to export due to the country's woefully inadequate infrastructure. With a declining economy, a history of conflict and corruption, and billions of dollars in external debt, the Democratic Republic of Congo will remain faced with hardship into the foreseeable future.

KEENE STATE COLLEGE

## Congo River

FROM ITS SOURCE on a savanna PLATEAU just south of Lake TANGANIKA, the Congo River flows some 2,880 mi (4,630 km) through equatorial africa before eventually emptying into the ATLANTIC OCEAN. While no other major river in the world transects the equator even once, the Congo River twice crosses the equator in its journey to the sea. The river flows through an immense and relatively flat drainage basin that lies more than 1,000 ft (300 m) above sea level. The Mitumba Mountains and the Ruwenzori Range form the eastern rim of the basin, while high plateaus rim the drainage basin in the north and south. A narrow westward outlet allows for the exit of the basin's surface water.

*Like its river and many tributaries in the region, the entire Congo basin is difficult to traverse.*

At 1.34 million square mi (3.46 million square km), the Congo River basin is the second-largest drainage basin in the world and receives an average of 60 in (152 cm) of rain annually.

This significant precipitation total is attributable to the fact that the river flows through both the Northern and Southern Hemispheres in a humid equatorial climate. As it is always the rainy season on one side of the equator, the Congo River avoids any notable change in volume from alternating wet and dry seasons.

By contrast, rivers in the savanna region of Africa often experience significant flow reductions during the dry season. Consequently, though only approximately 370 mi (600 km) longer than the NIGER RIVER, the Congo River discharges nearly eight times as much water into the Atlantic Ocean. Emptying into the ocean, the flow rate of the Congo River is second in the world behind only the AMAZON RIVER. However, as it is draining a basin in a humid equatorial climate, the tremendous discharge of the Congo River represents only 3 percent of its potential basin runoff.

Looping north and west in a great arc from its headwaters in the Katanga province, the Congo River receives input from several substantial tributaries. These rivers include the Kasai, Ubangi, Luvua, which

emanates from Lake Mweru in the far southeast, and the Lualaba, the principal stream of the upper course, considered by many to be the main branch of the Congo. In its relentless journey to the Atlantic Ocean, the width of the Congo varies from 3.5 mi (8 km) to 8 mi (12.8 km) and is divisible into three distinct sections—the Upper, Middle, and Lower Congo.

Characterized by waterfalls, lakes, and rapids, the Upper Congo includes a series of seven cataracts and rapids known as Stanley Falls. Extending over 60 mi (96 km), Stanley Falls demarcates the lower end of the Upper Congo and gives way to a lengthy stretch of navigable river along the Middle Congo. These navigable waters of the Middle Congo terminate just above Livingstone Falls and immediately downstream from the capital city of Kinshasha. A series of more than 30 cataracts, Livingstone Falls represents a turbulent 220 mi (354 km) stretch of the Congo River. Below the falls, the Lower Congo travels for approximately 200 mi (322 km) across the nearly level coastal plain before terminating in the Atlantic Ocean.

With an estuary approximately 7 mi (11 km) wide, the Congo River differs from other African rivers such as the Niger and the Nile in that it does not form a significant DELTA upon entering the ocean. However, it is similar to its African counterparts in that it has only limited navigability for significant portions of its course.

From its entry point into the Atlantic Ocean, for example, the Congo is navigable for only 85 mi (137 km) before reaching a series of rapids at the major fishing port of Matadi. Despite its inherent difficulty, river transport is an even greater necessity in the waters of the Congo than elsewhere in Sub-Saharan Africa. This same turbulence that renders many stretches of the Congo River impassable also contributes to the river's potential for hydroelectric power.

Owing to the speed and volume of its waters, the Congo River basin is the potential source of approximately 13 percent of the world's total hydroelectric power. Inga Falls, some 25 mi (40 km) upstream from the river port of Matadi, represents the largest hydroelectric power potential in Africa (and perhaps the world). Here water cascades downstream at a rate of 150,000 cubic ft (43,000 cubic m) per second as the river falls nearly 330 ft (100 m) in only 8.7 mi (14 km). Efforts to tap into the estimated 43,000 megawatts of generating capacity have thus far captured only a fraction of the potential power. Completion of two construction phases, Inga I (1972) and Inga II (1982), has netted only 1,700 megawatts of hydroelectricity. In

1999, plans for additional Inga stages were announced—with the ultimate objective being the capture of the entire power of Inga Falls by 2010. Despite its hydroelectric potential, concerns have been raised over the project's impact on the number of fish species and the viability of commercial inland fishing.

Like its river and tributaries, the entire Congo basin is difficult to traverse. Those pockets of the basin containing tremendous mineral wealth, including diamonds, cobalt and copper, have suffered intensive exploitation for decades. However, vast expanses of forest remain untouched and are home to such rare animals as the okapi and gorilla. Much of the forested basin has experienced only minimal human impact, such as when the Pygmies and other indigenous peoples use the forest for their hunting and gathering needs.

Agricultural activity typically includes the cultivation of bananas, maize, and sweet potatoes, as well as more commercially oriented crops such as coffee and sugar. Other economic activity involves raising goats and tending livestock. Despite only fairly limited economic exploitation of the region, the mineral wealth and hydroelectric potential of the Congo River basin are likely to attract increasing attention and activity in the future.

KEENE STATE COLLEGE

## Connecticut

CONNECTICUT IS the southernmost of the New England states in the northeastern UNITED STATES and

has borders with MASSACHUSETTS in the north, NEW YORK in the west, and RHODE ISLAND to the east. There is also a very small area in the very northeast corner where Massachusetts extends south creating an eastern border. To the south, the Long Island Sound separates Connecticut from New York's Long Island, while Block Island and the Block Island Sound separate the coastal region from the ATLANTIC OCEAN.

The state has a roughly rectangular shape, extending approximately 90 mi (145 km) from east to west and 55 mi (90 km) from north to south. There is a very small protrusion in the southeast that juts into New York along the Long Island Sound. With an area of 5,009 square mi (12,973 square km), Connecticut ranks 48th nationally in size. With a population of 3,405,565, however, the state ranks 29th nationally in total population and is 4th in terms of population density, with 703 persons per square mile (1,821 per square km). But the high-density ranking does not mean there is not a rural feeling as you travel around the state. Most of the people live in or around Hartford (the capital) or within the corridor that extends southeast to New Haven (home to Yale University), Bridgeport (the largest city at 135,529) and New York. Overall, the state's 10 largest cities account for only 28 percent of the state's population.

The state is easily divided into three distinct regions on an east-west basis, plus a narrow coastal region running east-west that provides a north-south distinction. The land in the west is part of what is generally referred to as the Western Highlands, a landform that extends northward into Massachusetts and Vermont. Here the land slopes downward as you move south and east. Steep hills, sharp ridges, and numerous streams characterize the rugged beauty of the Berkshires, part of the Taconic Mountains in the very northwestern portion of the state between the Housatonic River and the New York border. The state's highest point of 2,380 feet (725 m) above sea level is here on the southern slopes of Mount Frissell, whose main peak at 2,453 ft (748 m) is on the Massachusetts side of the border. The heavily forested Eastern Highlands, which extend from the Connecticut Valley lowland northeastward to MAINE, are not as high as the Western Highlands.

Running north-south down the middle of the state following the Connecticut River is the Connecticut River Lowland, a narrow strip of land approximately 30 miles wide (48 km), characterized by numerous small rivers and low hills. The southern coastal lowlands run along the southern shores of the state where the land meets the Long Island Sound. The area varies

from 6 to 16 mi (10 to 26 km) wide, contains numerous beaches and small harbors, and, because of the protection offered by Long Island, has become a popular summer resort retreat.

## HISTORY

The Dutch were the first Europeans to explore the area when Adriaen Block sailed through Long Island Sound and explored the Connecticut River in 1614. By 1633, the Dutch had built a small fort near present-day Hartford, but the area was abandoned in the 1650s as more and more English settlers arrived. As the Puritans came in increasing numbers, the population expanded so that by 1662, when the colony received a legal charter from the English to exist as a corporate colony, there were more than a dozen towns. Connecticut was the fifth of the original 13 colonies to ratify the new constitution, officially becoming a state of the United States in January 1788.

After the Embargo Act of 1807 ruined the shipbuilding industry, manufacturing became the centerpiece of the state economy as increasing numbers of tradesmen came to the area. The manufacture of firearms was one of the mainstays of the economy in the late 1700s, as craftsmen worked to turn Connecticut iron into patriot guns. Eli Whitney, inventor of the cotton gin, opened the first modern factory to mass-produce materials when he founded a firearms factory to produce guns with standardized interchangeable parts at New Haven in 1798. Textiles, silverware, sewing machines, and clocks and watches were among the state's early manufactured goods. The insurance industry, long a key word associated with images of the state's economy and Hartford, had its beginnings in 1810 when the Hartford Fire Insurance Company opened its doors for business.

Today, although famed for its rural character and village atmosphere, most of the wealth in Connecticut is derived from industry. The state is an important producer of jet engines and parts, electronics and electrical machinery, computer equipment, and helicopters. Firearms and ammunition, first produced here at the time of the American Revolution, are still made, and Groton, where the first nuclear submarine was built in 1954, remains a center for submarine building.

Because much of the manufacturing is related to military spending, Connecticut's heavy industry remains subject to the periodic ups and downs of the U.S. military budget. Fortunately, the growth of financial, insurance, real estate, and service industries has more than offset any declines brought on by manufacturing

downturns, helping to turn the state into one of the wealthiest in the nation. Connecticut ranks first in both per capita income (\$40,702) and disposable income per capita (\$32,655).

Agriculture accounts for only a small share of state income. The state's major agricultural products include dairy products, eggs, vegetables, tobacco, mushrooms, and apples. High-grade broadleaf tobacco used in making cigar wrappers has been an important agricultural crop since the 1830s. The fishing industry is relatively small and has been hampered recently by pollution in the waters of the Long Island Sound. Stone accounts for most of the income derived from mining as it has since the 1800s when the Brownstone Quarries at Portland provided stones for mansions and public buildings.

## containment

CONTAINMENT IS a political concept that served as the muted geopolitical battle cry for the UNITED STATES in the four decades of the Cold War (1947–89). It was first articulated in an embassy report from a young diplomat in Moscow dated February 22, 1946. In the “long telegram” George F. Kennan laid out a philosophical and conceptual framework for understanding the Soviet Union's approach to the world.

He pointed to a basic Russian psychic insecurity that underlay all their historic interactions with other nations, a sense of impending danger from the open STEPPE and a need for greater buffers and more impenetrable boundaries. Thus conflict with the Soviet Union was no shortcoming on the part of U.S. diplomacy but was more a perennial part of the Soviet perception of the outside world exacerbated by the flawed ideology of communism. Furthermore, it was the moral duty of the United States to stay its ground as the defender of personal liberty and democratic principles. This con-

flict was not a pragmatic case of give and take, rather a fight to the death between good and evil. Kennan called for a heroic struggle that had neither time limits nor geographical bounds.

This pathway of American moral imperative had powerful detractors from the beginning. Since it asked for the good fight to be fought at all points of the compass according to the “shifts and maneuvers of Soviet policy” it allowed no distinction between vital and peripheral interests. As the Truman Doctrine became a working reality around the world, Kennan’s view of political and economic containment gave way to the administration’s more martial strategy.

Sentiments from Europe embodied in the mighty voice of Winston Churchill called for the West to seek concession from the Soviet Union immediately while the U.S. atomic monopoly remained. Containment was patently defensive in nature, giving up the initiative to an aggressive adversary. Truman’s political opponents would call for a more aggressive “rollback” of the communist advance with a more proactive posture. The early criticism of former vice president Henry Wallace that questioned America’s moral right to wage an ideological and material war against communism, continued to plague the American mindset during the Cold War.

Kennan’s insights would become the basis of the Truman administration’s foreign policy. Stalin had proven to be an unreliable partner in the liberation and reconstruction of Europe. Instead the Kremlin chose to confound Western consolidation by instigating insurgency in GREECE and pressing communist parties to civil disobedience in Europe. As embers of discontent glowed among the ashes of Europe, Britain proved too weak to take up the crusade against a new threat to democracy.

The United States instinctively moved toward this moral challenge but needed more than the old world balance of power rationale. The administration saw the struggle against the Soviet Union as a struggle against two ways of life, a call to the protection of freedom everywhere. Here Kennan’s concept of containment gave an American vision and voice to the epic struggle. The Truman Doctrine took a moral high ground of supporting all free peoples who would resist subjugation by armed minorities or external forces. This meant immediate military and economic support to GREECE and TURKEY; Greece representing the European victims of World War II and Turkey the new American commitment to all nations struggling for freedom.

Each administration after Truman used the clarion call of containment as the framework of its foreign policy. Its lack of specifics regarding U.S. national interests caused much debate as to action. The countering of Soviet influence was seen to require the pouring of treasure into military bases around the world, the coffers of regional treaty organizations and power brokers, and weapons programs designed for the apocalypse. It also justified the shedding of blood in such diverse places as the Korean peninsula, the jungles of VIETNAM, and the islands of the CARIBBEAN SEA.

Former Secretary of State Henry Kissinger sees Kennan’s article rising to the level of historical philosophy, in calling the United States to a moral crusade heroic in proportion and idealistic in purpose. The United States could pursue its foreign policy in the spirit of righteously feeding the hungry, clothing the poor, and defending the weak. The Cold War has been won.

The Soviet Union dissolved and communism lapsed as a viable ideology among nations. Containment’s legacy in Europe is the NORTH AMERICAN TREATY ORGANIZATION (NATO), the EUROPEAN UNION, and the newly independent states of Eastern Europe eager to join in. The United States was left with an armed might of global proportions that was available for the handling of rogue regimes such as Iraq and AFGHANISTAN.

The concept of containment, in miniature, continues in the U.S. focus on an “axis of evil,” as U.S. President George W. Bush described Iraq, IRAN, and North KOREA.

## continental drift

CONTINENTAL DRIFT INVOLVES large-scale horizontal movements of continents relative to one another

and to the ocean basins during one or more episodes of geologic time. The hypothesis of large-scale movement or displacement of continents has a long history. About 1800, Alexander von Humboldt, a German naturalist, noted the apparent fit of the bulge of eastern South America into the bight of Africa. On the basis of this observation, he theorized that the lands bordering the ATLANTIC OCEAN had once been joined. Half a century later, a French scientist Antonio Snider-Pellegrini argued that the presence of identical fossil plants in both North America and European coal deposits could be explained if the two continents were formerly connected, and was difficult to account for otherwise. In 1908, U.S. scientist Frank B. Taylor invoked the notion of continental collision to explain the formation of some of the world's mountain ranges.

Building on the previous arguments, the first comprehensive theory of continental drift was introduced by Alfred Wegener, a German meteorologist. It was unusual that it attracted worldwide attention, caused scores of scientific papers to be written attacking or defending it, and still has many staunch and convinced adherents despite numerous grave theoretical difficulties. It has long been known that the continental portions of the earth's crust consist chiefly of the lighter and more acid rocks; beneath this, it was commonly supposed, there was a layer of denser and more basic rocks.

### FLOATING CONTINENTS

Wegener essentially proposed that the lighter continents are floating on the denser underlying material. By bringing together a large mass of geological and paleontological data, he postulated that for a large part of geological history there was but a single land mass or continent that covered about one-third of the globe. He called that single continent Pangaea, which late in the Triassic period (245 to 208 million years ago) fragmented, and the parts began to move away from one another. Westward drift of the Americas opened the Atlantic Ocean, and the Indian block drifted across the equator to merge with Asia. One of Wegener's chief arguments was the assertion that eastern North and South America would fit well into the outlines of western Africa and Europe.

In 1937 Alexander L. Du Toit, a South African geologist, modified Wegener's hypothesis by suggesting two primordial continents: Laurasia in the north and Gondwanaland (or Gondwana) in the south. Aside from the congruency of continental shelf margins across the Atlantic, modern proponents of continental

drift have amassed impressive geological and seismological evidence to support their views. Indicators of widespread glaciation from 380 to 250 million years ago are evident in ANTARCTICA, southern South America, southern Africa, INDIA, and AUSTRALIA. If these continents were once united around the south polar region, this glaciation would become explicable as a unified sequence of events in time and space.

Also, fitting the Americas with the continents across the Atlantic brings together similar kinds of rocks and geologic structures. A belt of ancient rocks along the Brazilian coast, for example, matches one in Africa. Moreover, the earliest marine deposits along the Atlantic coastlines of either South America or Africa are Jurassic in age (208 to 144 million years old), suggesting that the ocean did not exist before that time.

In the 1950s, interest in the concept of continental drift increased as knowledge of earth's magnetic field during the geologic past developed from the studies of geophysicists Stanley K. Runcorn, P.M.S. Blackett, and others. Ferromagnetic minerals such as magnetite acquire a permanent magnetization when they crystallize as constituents of igneous rock. The direction of their magnetization is the same as the direction of the earth's magnetic field at the time and place of crystallization.

### REMNANT MAGNETISM

Particles of magnetized materials released from their parent igneous rocks by weathering may later realign themselves with the existing magnetic field at the time these particles are incorporated into sedimentary deposit. Studies of the remnant magnetism in suitable rocks of different ages from all over the world indicate that the magnetic poles were in different places at different times. The polar wandering curves are different for the various continents, but in important instances such differences are reconciled on the assumption that continents now separated were formally joined. The curves for Europe and North America, for example, are reconciled by the assumption that the latter has drifted about 30 degrees westward relative to Europe since the Triassic period.

Increased knowledge about the configuration of the ocean floor and the subsequent formulation of the concepts of seafloor spreading and the theory of PLATE TECTONICS provide further support for the theory of continental drift. During the early 1960s, the American geophysicist Harry H. Hess proposed that new oceanic crust is continually generated by igneous activity at the crests of mid-ocean ridges, submarine mountains that

flow a sinuous course of about 37,000 mi (60,000 km) along the bottom of the major ocean basins. Molten rock material from the earth's mantle rises upward to the crests, cools, and is later pushed aside by new intrusions. The ocean floor is thus pushed at right angles and in opposite directions away from the crest. By the late 1960s, several American investigators, among them Jack E. Oliver and Bryan L. Isacks, had integrated this notion of seafloor spreading with that of drifting continents and formulated the basis for plate tectonic theory. According to the later hypothesis, the earth's surface, or lithosphere, is composed of a number of large, rigid plates that float on a soft (presumably partially molten) layer of the mantle known as the asthenosphere. The margins of the plates are defined by narrow bands in which 80 percent of the world's earthquakes and volcanoes occur. There are three types of boundaries.

The first of these is a very narrow band of shallow earthquakes caused by tensile stresses that follow exactly the crest of the 49,000-mi- (80,000-km-) long, active midocean ridges. The second boundary type occurs in areas where these ridges are offset. Earthquakes are much more violent along fault lines at such sites and results from the plates on either side of the faults grinding literally past one another in opposite directions.

Earthquakes forming the third boundary are distributed more diffusely but include all the world's deep earthquakes, that is, those originating at depths greater than 90 mi (145 km) and are associated with extremely narrow zones where the ocean floor descends below its normal depth to as much as 6.5 mi (10.5 km) below sea level—oceanic trenches. Across this margin, the maximum earthquake depths systematically increase along a dipping plane, with shallower earthquakes associated principally with the volcanic activity that borders each trench.

The ridge-crest earthquakes originate because of the tension created when the plates on either side move in opposite directions. This movement also releases the pressure on the underlying hot rocks, causing them to begin melting. The resulting magmas rise to form volcanoes (such as those in ICELAND), which then solidify and later fracture as the tensional forces reassert themselves. Such new volcanic rocks thus become added to the edge of each plate, which grows at these “constructive” margins.

The evidence for plate motion is not only the nature of the earthquakes but also the age of the volcanic oceanic rocks. Dating can be achieved by using both the fossil contents of the sediments overlying the vol-

canic rocks and the time record represented by the anomalies in the magnetism of the rocks, which can be detected by ships sailing on the ocean surface. These show that the youngest volcanic rocks are at the crest of the midocean ridges and the oldest are in the deepest areas, that is, the oceanic trenches. Nowhere, however, are such rocks older than 190 million years, indicating that all older oceanic rocks must have been destroyed.

The midocean ridges occur along some of the plate margins. Where this is the case, the lithospheric plates separate and the upwelling mantle material forms new ocean floor along the trailing edges. As the plates move away from the flanks of the ridges, they carry the continents with them. On the basis of all these factors, it may be assumed that the Americas were joined with Europe and Africa until approximately 190 million years ago, when a rift split them apart along what is now the crest of the mid-Atlantic Ridge. Subsequent plate movements averaging .8 in or 2 cm per year have brought the continents to their present position.

Although the lateral extent of the plates is well defined, their thickness is less certain. At the crest of the oceanic ridge they are very thin, but heat-flow and seismic evidence suggest that the basin increases rapidly with depth, reaching 30 to 36 mi (48 to 57 km) within about 6 to 12 mi (9 to 19 km) of the crest. By about 597 mi (960 km) distance from the crest, the basin has increased to 71 mi (115 km). A plate may be subducted at any thickness but rarely exceeds 90 mi (145 km). Moreover, the presence of volcanic rocks indicates that here the Earth's lithosphere is at least 118 mi (190 km) thick, so that mantle flow, which causes plate motions, must occur at even greater depths. It seems likely, though still unproven, that the breakup of a single landmass and the drifting of its fragments is merely the latest in a series of similar occurrences throughout geologic time.

## continental shelf

A CONTINENTAL SHELF is the submerged top of the continent's edge, lying between the shoreline and the continental slope that forms a border to a continent. In other words, the surface of the Earth lies at two general levels: a lower, which is the floor of the ocean basins, and an upper, the parts of which are the continents. Between these two levels is a comparatively narrow slope. The volume of ocean water is, however, a little too great to be entirely contained in the ocean basins, and so it must lap over somewhat on the lower, outer edges of the continental platforms. Such a submerged outer edge is called the continental self. The shelf is made shallower by deposition of material eroded from the land. The shelf has a gentle slope and is the shallowest portion of the ocean. Usually, a shelf is less than 650 ft (200 m) deep; in ANTARCTICA the continental shelf averages 1,650 ft (500 m).

The continental shelves are the regions of the oceans best known and the most exploited commercially. It is this region where virtually all of the petroleum, commercial sand and gravel deposits, and fishery resources are found. It is also the locus of waste dumping. Changes in sea level have alternately exposed and inundated portions of the continental shelf. A continental shelf typically extends from the coast to depths of 330 to 600 ft (100 to 200 m). In nearly all instances, it ends at its seaward edge with an abrupt drop called the shelf break. Below this lies the continental slope, a much steeper zone that usually merges with the section of ocean floor called the continental rise at a depth of roughly 13,000 to 16,000 ft (4,000 to 5,000 m).

The shelf varies greatly in width, but it averages about 40 mi or 65 km. Almost everywhere it represents simply a continuation of the land surface beneath the ocean margins; hence, it is broad and relatively level offshore from plains, and narrow, rough, and steep off mountainous coasts. For example, the shelf along the mountainous western coast of the United States is narrow, measuring only about 20 mi or 32 km wide, whereas that fringing the eastern coast extends more than 75 mi or 120 km in width. Exceptionally broad shelves occur off northern AUSTRALIA and ARGENTINA.

The continental slopes begin at the shelf break and plunge downward to the great depths of the ocean basin proper. Deep submarine CANYONS, some comparable in size to the GRAND CANYON of the Colorado River, are sometimes found cutting across the shelf and slope, often extending from the mouths of terrestrial rivers. The CONGO, AMAZON, GANGES, and HUDSON

rivers all have submarine canyon extensions. It is assumed that submarine canyons on the continental shelf were initially carved during periods of lower sea level in the course of the ice ages. Their continental slope extensions were carved and more recently modified by turbidity currents—subsea “landslides” of a dense slurry of water and sediment.

Some parts of the world's continental shelves are extremely level (for example, the parts off the Arctic coast of SIBERIA), but more commonly, they exhibit some relief. Close to the coast of New England are submerged glacial deposits. In places, ridges or cliffs can be traced from the land onto the continental shelf. Usually continental shelves are covered with a layer of sand, silts, and mud. In a few cases, steep-walled V-shaped submarine canyons cut deeply into both the shelf and the slope below. Some of them connect with a system of land valleys, but their origin is one of the great scientific puzzles.

Many continental slopes end in gently sloping, smooth-surfaced features called continental rises. The continental rises usually have an inclination of less than half a degree. They have been found to consist of thick deposits of sediment, presumably deposited as a result of slumping and turbidity currents carrying sediment off the shelf and slope. The continental shelf, slope, and rise together are called the continental margin.

Since the 1970s an increasing number of investigators have sought to explain the origin of continental shelves and their related structures in terms of PLATE TECTONICS theory. According to this theory, the shelves of the PACIFIC OCEAN, for example, formed as the leading edges of continental margins on lithospheric plates that terminate either at fracture zones (sites where two such plates slide past each other) or at subduction zones (sites where one of the colliding plates plunges into the underlying partially molten asthenosphere and is consumed, while the overriding plate is uplifted). Shelves of such origin tend to be steep, deformed, and covered by a thin layer of erosional debris. The Atlantic continental shelves, on the other hand, show little or no tectonic deformation and bear a thick veneer of sedimentary material.

They are thought to be remnants of the trailing edges of the enormous plates that split apart and receded many millions of years ago to form the Atlantic basin. As the edges of the plates gradually contracted and subsided, large amounts of sand, silt and mud from the continents settled and accumulated along the seaward side.

The Outer Continental Shelf (OCS) consists of the submerged lands, subsoil, and seabed, lying between the seaward extent of the states' jurisdiction and the seaward extent of federal jurisdiction. The continental shelf is the gently sloping undersea plain between a continent and the deep ocean. The United States OCS has been divided into four leasing regions. They are the Gulf of Mexico OCS Region, the Atlantic OCS Region, the Pacific OCS Region, and the Alaska OCS Region. In the United States in 1953, Congress designated the secretary of the interior to administer mineral exploration and development of the entire OCS through the Outer Continental Shelf Lands Act (OCSLA).

## continentality

**CONTINENTALITY** IS A climatic effect that results from a continental interior being insulated from oceanic influences. Winds and air masses of moderate temperature that originate over oceans move onshore to diminish differences in winter and summer temperatures in coastal areas of continents. Interiors of continents are too distant to experience the moderating effect. As a result, climates of continental interiors have great seasonal differences of temperatures and a mean annual temperature below the latitudinal average. Continental interior climates also tend to be subhumid to arid, as oceans are primary sources of atmospheric moisture.

Alexander von Humboldt, the celebrated 19th-century German geographer, was the first person to provide empirical proof that the climate of continental interiors differs from that of coasts. Through letter writing and extensive travels, he collected enough weather station data to draw the first world map of isotherms. (Isotherms are lines that join points of equal temperatures, and their patterns on a map reveal temperature trends over distance.) After examining the

map, von Humboldt concluded that continental climates are colder in winter and warmer in summer than places near oceans at the same latitude. He popularized the term *continentality* to describe the effect that a location's distance from an ocean has on its mean annual range of temperature.

Since von Humboldt's time, geographers and scientists have used other climatic elements to measure continentality, including precipitation, wind, and air mass frequency. Nevertheless, the most widely accepted criterion remains the mean annual range of temperature, which is the difference between a location's warmest and coldest average monthly temperatures. This facile calculation is a clear-cut expression of how climates of inland and coastal areas differ.

The spatial variation of the mean annual range of temperature is a result of differential heating of air by land and water. The differences in summer and winter temperatures over land and water are greatest.

In summer, air temperature over the ocean is cooler than over the land. There are several reasons for the difference. First, chemically, water has a higher specific heat than land does, meaning water must absorb more solar energy than rock and soil in order to be raised the same number of degrees in temperature. Water also heats more slowly than land does because solar energy passes tens of meters below the water surface before it is absorbed completely. Land heats up faster than water because heat conducts only a few inches (centimeters) and feet (meters) into the ground. Additionally, water stores heat at even greater depths than land does, as downwelling of water distributes absorbed energy hundreds of meters below the surface. Water undergoes high rates of evaporation in summer, which cools air temperatures by transferring sensible heat of water into air as nonsensible heat of vaporization.

In winter, the ocean is still in the slow process of transferring heat energy stored during the summer into the atmosphere. The belated transfer makes air over the ocean relatively warmer than that over land; conversely, winter air over land is cooler because summer heat is stored closer to the ground surface, causing land in winter to cool air faster and to a lower temperature than water does.

A main influence on the mean annual range of temperature on land is distance from the oceans. Three cities on the North European Plain that are progressively farther inland illustrate the effect. Antwerp, BELGIUM, is nearest the Atlantic Ocean; Warsaw, POLAND, is a mid-distance away; and Saratov, RUSSIA, is farthest from the ocean. In this example, latitude, which affects

sun angle and therefore intensity of solar energy, does not explain differences in mean annual temperature ranges of the cities, as the three are less than 1-degree latitude apart (between 51 degrees N to 52 degrees N). Therefore, distance from the ocean is the only major factor that could explain the differences.

The plain's open terrain gives all three cities potential access to the moderating effects of the westerlies, a belt winds that blows across the ATLANTIC OCEAN and carries marine heat and water vapor inland. However, temperature data show that the size of the mean annual temperature range increases with distance from the ocean. Antwerp's mean range is 26.6 degrees F (14.8 degrees C); Warsaw's is 35 degrees F (19.5 degrees C); and Saratov's range is 59.3 degrees F (32.9 degrees C). Antwerp has a moderate temperature range because it is within 50 mi (80 km) of the sea. Saratov's range is more than double Antwerp's because it is 1,600 mi (2,700 km) inland. Warsaw's temperature swing is between the two extremes, owing to its middle-distance location of 600 mi (950 km) from the ocean.

Mountains influence continentality by limiting the distance that maritime winds can enter continents. For example, NEVADA is coastal CALIFORNIA's inland neighbor and not far from the Pacific Ocean. However, the Sierra Nevada of California add to the continentality of Nevada by blocking marine air of the westerlies from the ocean. The absence of the ocean's humidity in Nevada leads to fewer clouds there. Clearer skies means Nevada has greater solar heating in summer and radiation cooling in winter than it would have if mountains were not present to block ocean air from entering. Additionally, blocking of moist ocean air causes aridity in Nevada.

Latitude also influences continentality. In the tropics, annual temperature swings usually are small even in continental interiors. In middle latitudes of the Northern Hemisphere, the continental effect is an overriding factor in climates of continents, as average annual temperature ranges increase with increasing latitude there. In the middle latitudes of the Southern Hemisphere, the effect of continentality is smaller, as continental areas are less massive in that part of the world.

In areas poleward of the middle latitudes, the polar night and ice cover introduce complications, so it is difficult to separate influences of land or sea in terms of temperature or other climate variables. Climate scientists have developed several formulas to correct temperature range for polar latitudes.

KUTZTOWN UNIVERSITY

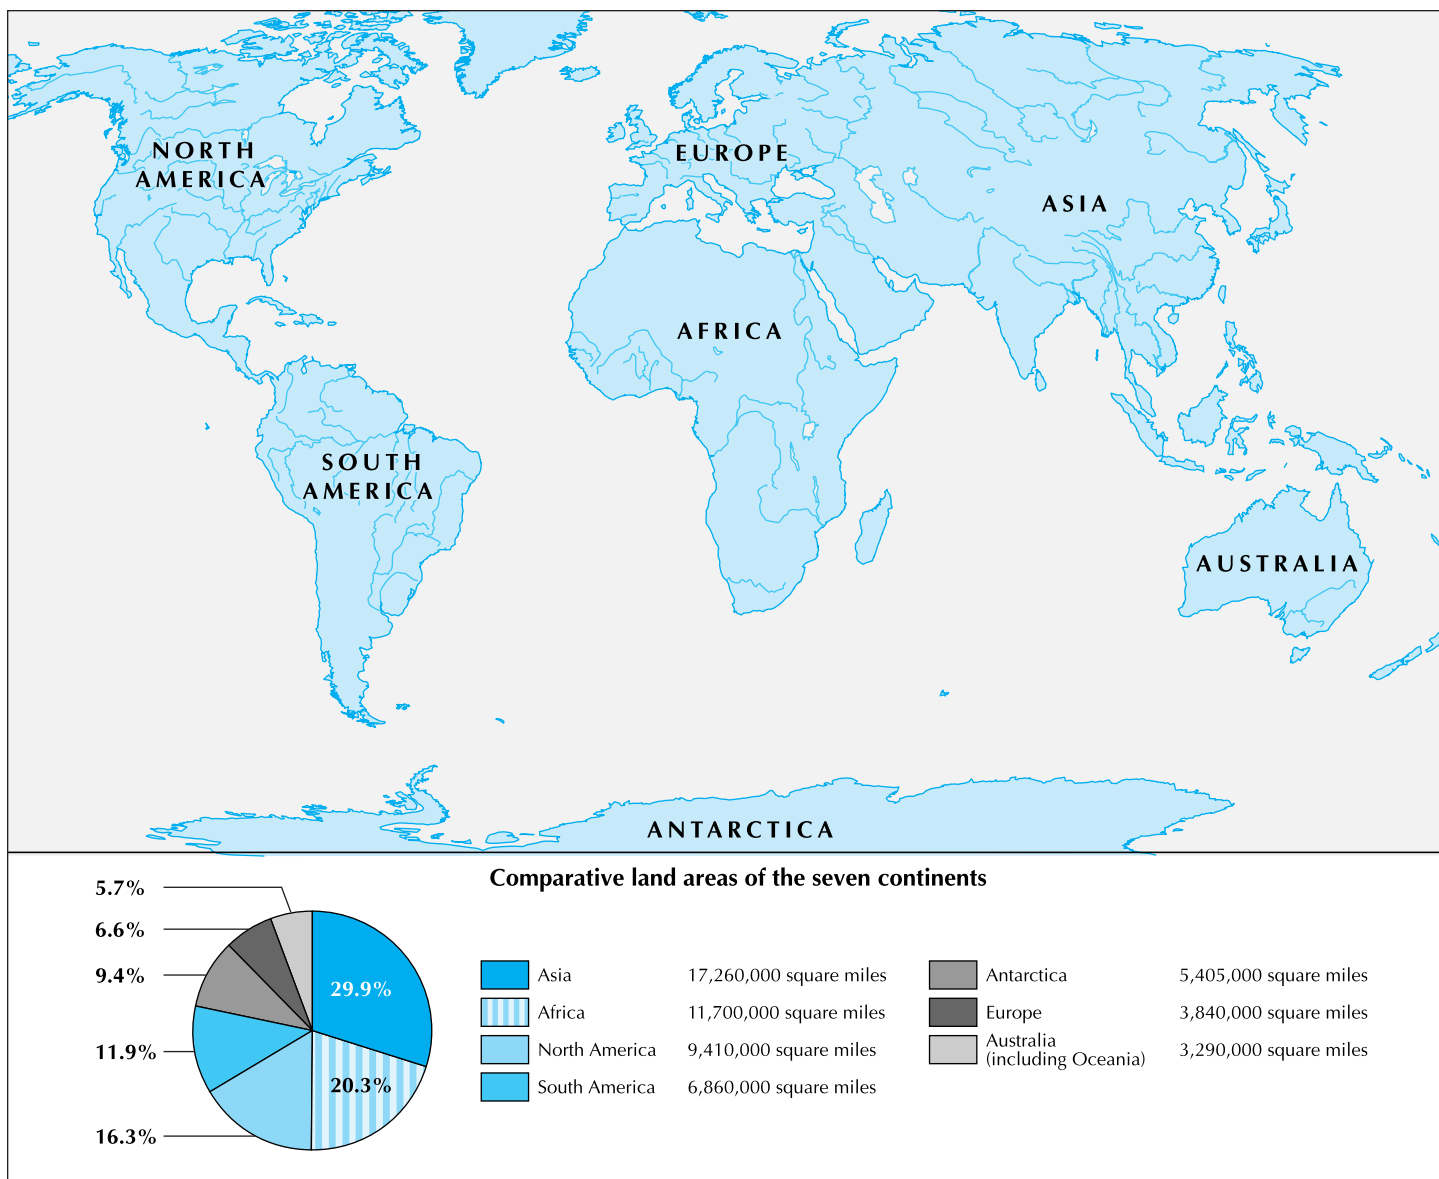

## continents

THE EARTH IS AN ocean-dominated planet. Only one-third of the planet's surface is dry land. The Earth's land areas include innumerable islands and several larger expanses of land termed continents. A continent is defined as a mass of land significantly larger than an island, completely or nearly surrounded by ocean water. By common agreement among geographers, the Earth's smallest continent is AUSTRALIA while the Earth's largest island is GREENLAND. Australia's area is about 2,966,000 square mi (7,682,000 square km), while the area of Greenland is approximately 836,000 square mi (2,165,000 square km).

The outermost rock layer of the earth is termed the crust. The oceanic crust is composed almost entirely of basalt, a dense igneous rock. The earth's continental crust, in contrast, is composed largely of lighter granitic rock. The continental crust varies greatly in thickness but averages about 35 mi (56 km) thick. The oceanic crust, in contrast, averages only about 4 mi (6 km) thick. Because of the imprecision of the definition, geographers do not agree on the number of the earth's continents. Geographers in the United States commonly recognize seven continents: Asia, Africa, North America, South America, Antarctica, Europe, and Australia.

The ancient Greeks recognized three continents bordering and surrounding the MEDITERRANEAN SEA (the "sea in the middle of the lands"). Africa was almost completely separated from Asia by the RED SEA, while Asia was separated from Europe by the AEGEAN SEA, the Dardanelles, the Sea of Marmara, the Bosphorus, and the BLACK SEA. In later centuries, when exploration revealed that Europe was in reality not a separate landmass, Europe was redefined to include extensive land boundaries—in violation of the generally accepted definition of a continent. The boundary between Europe and Asia is now generally accepted to begin at the Aegean and to continue through the Dard-

anelles, the Black Sea, the CAUCASUS MOUNTAINS, the CASPIAN SEA, the Ural River, and the URAL MOUNTAINS. The Ural Mountains thus separate European Russia from Siberia.

In lists of continents compiled outside the United States, Europe and Asia are often combined as Eurasia. And since Africa and Asia are connected at the Suez Peninsula, Europe, Africa, and Asia are sometimes combined as Afro-Eurasia or Eurafrasia. The International Olympic Committee's official flag, containing five interlocking colored rings, symbolizes the five continents that send athletes to the Olympic Games: Europe, Asia, Africa, Australia, and the single continent of America (North and South America being connected at the Isthmus of Panama). Antarctica, the uninhabited continent, is unrepresented. In modern times, artificial

canals have been dug to connect oceans at both Suez and PANAMA. Along with the Red Sea, the Suez Canal is now sometimes said to separate Africa from Asia. The PANAMA CANAL, likewise, is sometimes considered to mark the boundary between the North and South American continents.

All of the continents except Antarctica are roughly triangular in shape, narrower in the south than in the north, a consequence of the way the early super-continental landmass of Pangaea broke apart. Two-thirds of the landmass of the continents occurs in the Northern Hemisphere, particularly in the hemisphere centered on Europe. The large landmass of Eurasia is balanced on the other side of the globe by the large water mass of the South PACIFIC OCEAN. The continental landmass of Antarctica is countered by the ARCTIC OCEAN.

U.S. Navy ships transit the Suez Canal, which is often used to demarcate the continents of Asia and Africa.

A subcontinent is a subdivision of a continent, a large peninsula that may be separated from the rest of the continent by geographic features of some kind. The most widely recognized subcontinent is the Indian subcontinent, the large peninsula jutting southward from the mass of Asia, isolated from the rest of Asia by the HIMALAYAS. In British English, “the subcontinent” usually refers to INDIA, PAKISTAN, BANGLADESH, and adjacent areas—in the same way that to the British “the continent” refers to the continent of Europe. If one considers Eurasia a continent, though, Europe is merely a subcontinent attached to the larger continental landmass. Other subcontinents might include the Arabian Peninsula of southwestern Asia, the southern cone of South America, and ALASKA (the northwestern peninsula of North America).

Continents are fringed by CONTINENTAL SHELVES, offshore areas of relatively shallow oceanic water. Shallow waters, with depths up to 600 ft (180 m), roughly follow the outline of the continents, up to the point where the continental slopes quickly drop off to the usual oceanic depths of 12,000 ft (3,660 m) or so. In places such as the Grant Banks east of Newfoundland, the continental shelf can be 250 mi (400 km) wide. In other places, especially along tectonically active coastlines such as CALIFORNIA, the continental shelf may be almost nonexistent.

A continental divide is the line along the backbone of a continent separating the drainage basins of the oceans surrounding that continent. The continental divide of North America follows the ROCKY MOUNTAINS

from Alaska south to MEXICO, and is then continued through Mexico’s Sierra Madre Occidental and the mountains of Central America to Panama. Streams to the west of this divide feed rivers that run to the Pacific Ocean. Streams to the east flow eventually to the ATLANTIC OCEAN or to its connecting seas (Hudson Bay, the Gulf of Mexico, or the CARIBBEAN SEA).

## Cook Islands

PART OF NEW ZEALAND, the Cook Islands consist of 15 islands in the south PACIFIC OCEAN, about halfway between HAWAII and NEW ZEALAND. They are about the same size as RHODE ISLAND. The islands are scattered over an area of more than 706,566 square mi (1.83 million square km). The nine islands in the southern group were formed by volcanic material escaping from a fracture in the Earth’s crust. Most of the population lives on these fertile islands. The northern islands are low coral atolls. The mountainous Rarotonga in the southern group is the largest island.

The Cook Islands have a tropical climate, moderated by trade winds, similar to Hawaii’s climate. It is often sunny, and the rains, although sometimes heavy, don’t last long. Hurricanes can occur during their summer, from December to March. The interior of Rarotonga is the wettest place in the islands. The highest temperatures, averaging 84 degrees F (29 degrees C), occur during the wet season. In the coolest months, the average daily high temperature is 77 degrees F (25 degrees C). Lush vegetation grows on the Cook Islands. Tall trees, creepers, and ferns grow in the interior. Food plants, such as coconuts, bananas, and grapefruit are found on the coast. Yams and taro are important food crops.

Most Cook Islanders are of Polynesian background, although a few people are a mix of Polynesian and other cultures. The Polynesians belong to the Maori branch of the Polynesian race and are related to

the Maoris of New Zealand. The official languages are English and Maori, and most people speak both. The overwhelming majority of the people are Christian. Most belong to the Cook Islands Christian Church, founded in the 1820s by missionaries. Cook Islanders are excellent dancers. Traditional music is also popular. Islanders compete in dance and singing competitions. String bands use a combination of electronics and traditional instruments fashioned from coconut shells. Visitors can choose from a large selection of arts and crafts made by the Islanders. Popular items include coconut-fiber hats, brightly-colored wraparound clothing, wood carvings, and pottery. Woven mats and blankets are also in demand, as are carved bowls.

Avarua, located on Rarotonga, is the nation's capital and largest town. Although it is a typical small tropical town, it boasts a gallery, the National Cultural Centre, and a branch of the University of the South Pacific. A number of small villages are scattered around the islands.

The Cook Islands have been occupied by the Polynesians for 1,500 years. Captain James Cook discovered some of the islands in 1773. Missionaries from London, converted most of the islanders to Christianity. The islands were a British protectorate from 1888 until 1901, when they were annexed by New Zealand. Although still officially a part of New Zealand, the islands are self-governing.

## core and periphery

CORE AND PERIPHERY are terms used in geographic models to describe areas of differing economic production and political power and can be applied to both intra- and interstate variations. Core areas are described as the engines of economic growth and are characterized by modern, technologically advanced production methods as well as highly skilled and high-wage labor. Places using low-technology production methods accompanied by low skill and low-wage labor, on the other hand, are labeled the periphery.

Within the discipline of geography, the terms *core* and *periphery* are more common in the subdiscipline of political geography as compared to economic geography, where they have been deemphasized in favor of more complex notions of flows and processes.

The concepts of core and periphery can be applied to various scales. At the interstate scale, examples of core areas are the UNITED STATES, the countries of Western Europe, and JAPAN. In these countries goods are produced using technologically complex methods, wages are high, and the labor force is relatively educated and skilled.

Countries like CAMBODIA, BANGLADESH, and most of Sub-Saharan Africa are examples of the periphery, where technologically simple, labor-intensive, low-skill, and low-wage occupations predominate. These are broad generalizations and within a country there can be areas of core processes and areas of peripheral processes. In the United States, for example, Silicon Valley in CALIFORNIA is a core area where high-technology businesses are clustered. Appalachia, on the other hand, is a peripheral area where technology is less complex and wages are low. Going down to even smaller scales, within a city core and peripheral areas can be spatially designated. In NEW YORK CITY, Wall Street and the financial district would represent a core area and some of the underdeveloped neighborhoods in the outer boroughs would be considered peripheral.

Although core and peripheral areas are often mapped, they are not place-based phenomena, but rather are characterized by the production processes present. Therefore, where core and peripheral processes are located, as well as what constitutes core and peripheral processes, can change over time. In each particular historical era core processes are the most technologically advanced production methods present. In the 19th century, core processes were characterized by the industrialized mass production of goods, such as textiles, in places like Manchester, England. In the present day, however, textile production is a peripheral production process common in countries of the global south. More technologically advanced computer and financial businesses predominate in core areas.

### THEORIES OF CORE AND PERIPHERY

The terms *core* and *periphery* are used in many contexts, but surprisingly the two main theories of core and periphery disagree on what the outcome of this economic differentiation will be. On the one hand, exchange-based theories of core and periphery predict long-term lessening of economic inequalities as core

areas develop the periphery and bring it up to an equal economic level. On the other hand, world systems theory predicts that the uneven development will be maintained as core areas exploit the natural resources, both commodities like timber and coal as well as cheap labor, in peripheral areas, which will further economic disparities.

### WORLD ECONOMY

The exchange-based model of core-periphery relations is often associated with the writings of John Friedmann (1966), who first noted these economic differences in VENEZUELA. Exchange-based models rely on the notion that market forces, if undisturbed by state regulation, will eventually result in spatial economic equality. These theories suggest that the cheaper costs of labor and raw materials in peripheral areas will encourage businesses to invest there, which will bring development. This idea, often known as developmentalism, is the underlying theory used by most governments in the world and by international organizations like the World Bank (WB), the International Monetary Fund (IMF), and the World Trade Organization (WTO) to promote free trade and economic reforms involving the deregulation of markets.

Critics of developmentalism have pointed out that over time economic disparities have widened rather than converging as the exchange-based models predicted. As an alternative, these scholars suggest world systems theory, also known as the world economy model, to explain core-periphery economic development. World systems theory was first proposed by Immanuel Wallerstein (1974) as a model to explain the persistence of worldwide economic disparities historically. The world economy model focuses on the role countries play at the global scale and argues that there is one world economy driven by capital accumulation that has been in place for approximately the last 500 years.

A unique aspect of the world economy model is the way power is understood. The model suggests power is derived from a country's ability to control situations through active force (waging war), latent force (threatening action), non-decision making (avoiding issues by never discussing them), and structural position. Core countries utilize their structural position by setting market prices and wages, controlling the economic agenda through international organizations (WB, IMF, WTO), and promoting free trade and open borders.

Technological advances are likely to occur only in the core because of the superior infrastructure present,

which maintains the core countries' structural advantage. Consequently, in the world economy model, the core is often described as the exploiter and the periphery as exploited.

World systems theory also adds a third category, the semi-periphery, which mediates between core and peripheral areas, stabilizing the system. The semi-periphery, rather simply, is characterized by both core and peripheral processes. At the interstate scale, countries like SOUTH AFRICA or INDIA are currently examples of this intermediate level. In India, core processes are present in cities like Bangalore and Mumbai where high technology businesses are clustered. However, in other parts of India there are millions of people who work in subsistence agriculture and earn less than one dollar a day.

Critics of the world economy model point out that although the model suggests that the core has a structural advantage that allows it to maintain, and even strengthen, its position through unequal exchange of capital, several countries have been able to escape the periphery. Recent examples are countries like SINGAPORE and South KOREA, which have increased their gross domestic product rapidly in the past 50 years. Additionally, the United States, which is the strongest state in the core today, was a peripheral country 300 years ago.

Finally, both world systems and exchange-based models of core and periphery are criticized for their use of static categories that do not adequately reflect complexities and variations on the ground. Although the terms *core* and *periphery* imply that discrete categories exist that are homogeneous within them and heterogeneous between them, in reality it is better to think of a continuum that flows between each level in these geographic models.

UNIVERSITY OF WISCONSIN, MADISON

## Costa Rica

**Map Page** 1136 **Area** 19,729 square mi (51,100 square km) **Population** 3,896,092 **Capital** San Jose **Highest Point** 12,500 ft (3,810 m) **Lowest Point** 0 m **GDP per capita** \$8,300 **Primary Natural Resources** coffee, bananas, agricultural products.

THE REPUBLIC OF Costa Rica, home to almost 3.9 million people, is located in Central America between NICARAGUA and PANAMA with CARIBBEAN SEA and PACIFIC OCEAN coastlines. With a narrow Pacific coastal region, Costa Rica is covered by rugged mountains with peaks over 12,000 ft (3,657 m) high, cutting the country from northwest to southeast. The chain contains several major volcanoes, one of which, Irazu, erupted destructively in the mid-1960s. Costa Rica suffers from occasional hurricanes, earthquakes, and floods in addition to volcanoes.

The coastal plains are low and subject to flooding, as well as being quite hot, humid, and heavily forested. The traditional Costa Rican economy was based upon the agricultural production of these coastal plains, where it is possible to cultivate an abundance of bananas, cocoa, and sugarcane. In contrast to the wet coastal plains, the Nicoya peninsula located in the northwest region of the country is made up of more arid plains. There, extensive cultivation of cash crops like sugarcane is not possible. Instead, these plains have been used by ranchers to raise large herds of cattle and by some farmers who grow grains.

The Central Valley lies between the mountain ranges and volcanoes, where the most productive land is found and coffee is cultivated extensively. Also, under the threat of an eruption, the majority of population lives in the Central Valley, which is the heart of the country and is renowned for its almost constant springlike climate. In addition, Costa Rica has sovereignty over a small island about 300 mi (482 km) off its Pacific Coast, known as Cocos Island, which is celebrated for its natural beauty.

The climate of Costa Rica is tropical and subtropical. The dry season lasts from December to April, while the rainy season lasts from May to November. While it is quite hot and humid along the coastal plains, the Central Valley and the highlands are much more agreeable. In some areas of the highlands, the

temperature varies greatly from that of the coastal areas.

Costa Rica is a democratic republic separated and administered in the form of seven provinces. The executive branch is made up of a president and two vice presidents, a unicameral legislature, and a Supreme Court.

Costa Rica is one of the most stable countries in the Americas; only two very brief periods of instability have taken place since the late 19th century. As a result of the stability, the government has been able to disband the military and to concentrate on economic development.

Even though Costa Rica is still mostly dependent upon its agricultural exports, diversification of the economy has succeeded in moving the country away from monocultures. After the success of government initiatives, Costa Rica is now home to expanding ecotourism and technology sectors. Consequently, the standard of living is high, especially relative to neighboring countries, and land ownership in the country is widespread.

WIDENER UNIVERSITY

## Côte d'Ivoire

**Map Page** 1113 **Area** 124,501 square mi (322,460 square km) **Population** 17,327,724 **Capital** Yamoussoukro **Highest Point** 5,748 ft (1,752 m) **Lowest Point** 0 m **GDP per capita** \$669 **Primary Natural Resources** petroleum, natural gas, diamonds, manganese.

CÔTE D'IVOIRE (Ivory Coast) is bordered by MALI and BURKINA FASO on the north, by LIBERIA and GUINEA on the west, and by GHANA on the east. The official capital is Yamoussoukro, while the largest city and commercial center of the country is the former capital, Abidjan.

The south consists of a coastal lowland with heavy rainfall, the interior of a densely forested plateau, and the north of upland savannas. There are over 60 ethnic groups in Côte d'Ivoire, the major groups being the Baoule, Beti, Malinke, Senufo, Anyi, and Dan. Of the more than 5 million non-Ivoirian Africans living in Côte d'Ivoire, one-third to one-half are from Burkina Faso, and the rest are from Ghana, Guinea, Mali, NIGERIA, BENIN, SENEGAL, Liberia, and MAURITANIA. The non-African expatriate community includes roughly 130,000 Lebanese and 20,000 French. About 60 percent of the population is Muslim (who live predominantly in the north), 25 percent follow traditional religious beliefs, and 15 percent are Christian (who are mostly concentrated in the south). French is the official language.

Côte d'Ivoire showed remarkable political stability from its independence from France on August 7, 1960, until late 1999. The first president was Félix Houphouët-Boigny, who remained in that position until his death in December 1993. He was succeeded by President Henri Konan Bédié, who was toppled by a bloodless coup by General Robert Guei on December 24, 1999, as falling world market prices for Côte d'Ivoire's primary export crops of cocoa and coffee put pressure on the economy. Elections were scheduled for fall 2000 but were later cancelled by Guei, and this started a period of coups, attempted coups, and civil wars, which ended only in January 2003, when French troops intervened to broker a power-sharing national reconciliation government.

Despite steady industrialization since the 1960s and a high economic growth rate from its independence through the 1970s, the country is still predominantly agricultural, which contributes 29 percent to the gross domestic product and employs approximately 68 percent of the population. Côte d'Ivoire is among the world's largest producers and exporters of coffee, cocoa beans, and palm-kernel oil. Other exports include cotton, bananas, pineapples, rubber, and mahogany and other hardwood timbers. Among the country's industries are the production of foodstuffs, palm oil, petroleum and natural gas (offshore production began in the early 1980s), textiles, construction materials, and fertilizer, and the assembly of motor vehicles and bicycles. Côte d'Ivoire, or Ivory Coast, was named for the supplies of ivory brought to the coast for trade in colonial times.

CLAUDIO O. DELANG  
FRANKLIN COLLEGE, SWITZERLAND

## Croatia

**Map Page** 1133 **Area** 22,000 square mi (56,542 square km) **Population** 4,422,248 **Capital** Zagreb **Highest Point** Dinara 604 ft (1,830 m) **Lowest Point** 0 m **GDP per capita** \$8,800 **Primary Natural Resources** oil, coal, bauxite, hydropower.

CROATIA IS AT once one of the oldest and newest states in Europe. There has been a Croatian state of some kind, with varying degrees of independence, since the 9th century. Croatia was one of the first to break away from the disintegrating Yugoslav Federation in 1990 and is today one of the more successful economies in the Balkans. Unlike Serbia and many of its other neighbors, Croatia has had closer ties to the West for centuries, as Catholics rather than Orthodox, and as subjects of Western rulers rather than Turkish sultans like their neighbors to the south and east. Today, Catholicism is regaining importance in Croatian national identity.

The physical shape of Croatia is reminiscent of a croissant, the symbol of defiance to Turkish invaders in the 17th century: The inland (or Pannonian) region consists of Croatia proper (with the capital, Zagreb) and Slavonia to the east. The coastal region consists of Istria and Dalmatia, extending along the ADRIATIC SEA coast for nearly 1,200 mi (2,000 km). The coast is dominated by inlets and over a thousand islands, creating a coastline of 3,618 mi (5,835 km). Only 69 of the islands are inhabited, the largest being Krk, Brac, and Cres. The interior consists of flat plains along the Hungarian border and the river valleys of the Drava and Sava (tributaries of the DANUBE to the east), and low mountains. The climate here is continental, differing sharply from the Mediterranean climate along the

Adriatic. High mountains divide these two regions, extensions of the Julian and Dinaric Alps that run north to south from Istria to Montenegro. Croatia borders a number of countries, mostly former members of Yugoslavia: SLOVENIA to the northwest, SERBIA AND MONTENEGRO to the east and south, and BOSNIA AND HERZEGOVINA to the east. HUNGARY lies across the Drava to the north.

### EARLY HISTORY

Much of Croatia's history is dominated by Hungary, first in a personal union between the Croatian and Hungarian royal families dating from 1102, followed by outright incorporation within the Hungarian kingdom from the 18th century. Croatia formed the highly militarized frontier between the Hapsburg and Ottoman dominions for several centuries. The coastal provinces of Dalmatia and Istria had a different history, however, falling under the administration of the Venetian Republic from the early 15th century. The famous maritime republics of Ragusa and Spalato were founded by Venetians and today (as Dubrovnik and Split) remain two of the most famous tourist destinations in the Mediterranean. At the end of World War I, Croatia and Dalmatia joined together as a component state within the new kingdom of the Serbs, Croats, and Slovenes, later renamed Yugoslavia.

Today's Croatian economy is split evenly between agriculture and industry. The best farmland is in the far northeast, where corn, wheat, and fruits are grown. Timber is also a significant resource in this area. Industry is mostly light, concentrating on chemicals and plastics, plus some extractive products such as coal, petroleum, and bauxite. Privatization delays and unemployment are Croatia's biggest issues today, as it works toward full membership in the EUROPEAN UNION. Tourism is on the rise as the region becomes more secure and is currently Croatia's biggest source of revenue. The Dalmatian coast is sunny and warm year-round, and is called the Riviera of the Adriatic. Dubrovnik was heavily damaged during warfare in the early 1990s but has been rebuilt under its status as a United Nations World Cultural Heritage Site.

SMITHSONIAN INSTITUTION

## Cuba

**Map Page** 1137 **Area** 68,885 square mi (110,860 square km) **Population** 11,263,429 **Capital** Havana **Highest Point** 6,578 ft (2,005 m) **Lowest Point** 0 m **GDP per capita** \$2,700 **Primary Natural Resources** sugar, tobacco, citrus, coffee, rice.

CUBA, THE 15th largest island in world, is part of the West Indies in the CARIBBEAN SEA. This island, which experiences a subtropical climate and a wet summer season between May and October, is composed of fertile ground where tobacco, sugarcane, and coffee are grown and where cattle graze. Twenty-five percent of the island is covered by the Oriental, Central, and Occidental mountain ranges.

More than 6,000 plant species are spread across Cuba. The royal palm is the most noticeable, and supposedly 20 million palms exist across the island. Cork palm can also be found on the island, as well as the palma barrigona, the ceiba, and the mariposa. The southern coast supports swamps with fish and birds.

Reptiles are the most abundant fauna. Crocodiles, iguanas, salamanders, lizards, and turtles, as well as a mixture of nonpoisonous snakes, are present throughout the country. The *jutia* (a tree rat) is the largest land mammal on the island. And the world's smallest bird, the bee hummingbird, originates from Cuba.

Modern-day history of Cuba can be traced back to November 27, 1492, when Christopher Columbus landed on the island. For the next 300 years, Spain had control over the small island. During the 16th century, the indigenous Tainos were virtually obliterated from the island. Subjected to a life of labor under the Spanish *encomienda* system, these indigenous people were forced to mine for silver and gold and to work the many plantations spread across the island.

Overall, the Spanish found a limited amount of silver and gold on the island. As the years passed, it was obvious that Cuba would have to serve other purposes for the Spanish administration. The island became a stopover for ships carrying goods from the Americas to Europe. In 1607, Havana was created as the Cuban capital. The forests across the island were cut down to make room for livestock, tobacco, and sugar for European sale. However, after the defeat of the Spanish Armada in 1587, Spain's New World colonies, such as

Cuba, suffered from a lack of central control. The unregulated West African slave trade flourished and pirates appeared in Cuban ports.

In 1762, 200 English warships with 20,000 troops appeared outside of Havana. After 44 days, Havana fell to the English, but within a year, the British traded their new possession back to SPAIN for the land of FLORIDA. The new king of Spain, Charles III, began to actively encourage free trade, and the Cuban economy prospered. By 1820, Cuba held the distinction of being the world's largest sugar producer. By 1835, all the New World colonies of Spain had received independence, except for PUERTO RICO and Cuba. Cuban revolutionaries began to form protests. In 1868, slavery was finally abolished and an overall rebellion for independence rose throughout the land. Ten years of war lasted and around 200,000 people perished in the fighting; some 100,000 fled the island. The Pact of Zanjón was signed in 1878, which ultimately granted all the rebels amnesty. However, independence was still not granted.

Cuban exiles in the UNITED STATES, including the poet José Martí, began plans for the next wave of rebellion. In 1895, they landed on eastern Cuba, and Martí was fatally shot. The rebels continued to fight, and in return, the Spanish government executed public figures and threatened civilians. Cuba eventually agreed to a home rule government for the Cubans, but the Cuban citizens wanted full independence.

In 1898, the U.S. warship *Maine*, anchored in the harbor in Havana, exploded. Although the reason for the explosion was unknown, American newspaper reports blamed the Spanish. American troops were dispatched to the island and the Spanish-American War began.

After various victorious American battles, including the Battle of San Juan Hill, a peace treaty was signed in December 1898. Although the Cubans were now independent of Spain, the U.S. influence on Cuba began. In 1902, the United States granted Cuba full independence but, under the Platt Amendment, reserved the legal right to intervene militarily if Cuba's independence was threatened. The Guantánamo Bay naval base was also leased by the United States, and is still currently occupied by the U.S. military.

By the 1920s, over two-thirds of Cuba's farmland was owned by American companies. Into the 1950s, Cuba was ruled by a number of military and political figures. During the early years of the Great Depression, President Gerardo Machado y Morales violently ended civil unrest throughout the country. He was overthrown in a coup, and Fulgencio Batista gained power,

which would last for more than 20 years. Throughout this period, Cuba suffered economically, and active resistance groups were formed.

Fidel Castro emerged as a very influential rebel leader. In 1953, he led an attack on the Moncada barracks in Santiago. More than 100 died, and Castro faced a public trial. He was jailed but given an early release. He was exiled to Mexico, and from there organized the 26th of July Movement. In December 1956, Castro and his group landed on the eastern part of the island. For three years, guerrilla warfare spread throughout the island. On January 1, 1959, Batista was overthrown and fled to the DOMINICAN REPUBLIC.

Castro became the prime minister of the country, and overhauled the economy. He nationalized much of the land and American-owned petroleum facilities. The United States in return cut sugar imports, which debilitated the economy. With a deteriorating economic situation, Castro turned to the Soviet Union for aid. Sugar trade thus developed between Cuba and the Soviets.

### BAY OF PIGS

In 1961, the U.S. CIA organized an invasion in the Bay of Pigs. Fourteen hundred CIA-trained Cuban exiles attacked Castro forces but were quickly captured. Castro declared that Cuba was to be a socialist state. The Soviet Union sent food, supplies, and nuclear missiles to the island that was only 90 miles off the coast of superpower rival, the United States. After an extremely tense nuclear standoff in 1962 between Cuba, the United States, and the Soviet Union, the missiles were returned to the Soviets.

For the next three decades, Cuba became a leading military and political force in the Third World, but its economy fell into major disrepair. In 1989, after the collapse of communism in Eastern Europe and the decline of the Soviet Union, RUSSIA withdrew its aid. In 1991, economic reforms began in the country. Cuban citizens were allowed to be self-employed and farmers' markets were opened. Slowly, the Cuban economy grew. Sensing that Castro's power base was declining, the United States passed the Helms-Burton Act, which imposed harsher embargo conditions on Cuba. In 2004, Castro's hold on Cuba was still strong and the country remained one of the last socialist states in the world.

## cultural geography

CULTURAL GEOGRAPHY IS a subdiscipline of HUMAN GEOGRAPHY. The founding father of cultural geography in North America is Carl Ortwin SAUER, and most of the research in cultural geography from the 1920s to the beginning of the 1980s was carried out by cultural geographers walking in the footsteps of Sauer and the so-called Berkeley School. In this tradition, cultural geography is concerned with material facets of culture. On the agenda of the Berkeley School were cultural influences on, and shaping forces of, the transformation of landscape and the natural environment. In short, the role that culture plays as an agent of these changes.

In this respect, the American tradition of cultural geography of the 20th century was a dominating and highly influential one. Since the end of the 1970s, however, cultural geography in the anglophone scientific community took on a different face. Drawing heavily on British cultural studies, focusing on interpretative and empirical methods, and refurbishing social theory, cultural geographers of that time developed the so-called new cultural geography. The mere amount of studies and research that has been carried out until today under the banner of this new cultural geography, and also the colorful, true-to-life, and rich array of topics hosted by the discipline, made new cultural geography probably the most successful subdiscipline of geography throughout the last 30 years. This boom, the beginnings of which are often referred to as the cultural turn in geography, has changed the discipline fundamentally. Nevertheless, recently there has been a vivid, critical discussion about the shortcomings of these new cultural geographies, which is revolving around the topics of the dangers of a holistic culturalist approach and the dematerialization and the (missing) political potential of the new cultural geography.

### THE NEW CULTURAL GEOGRAPHY

Turning away from environmental determinism and the regional tradition of the geography of his time, but drawing nevertheless on some aspects of both tradi-

tions, Sauer developed his own concept of cultural geography. Driven by an interest in historical processes and sequences and their influence on the natural environment, he was influenced to a certain degree by the German geographers Eduard Hahn and Alfred Hettner and the anthropogeographic tradition associated with Friedrich Ratzel, who was one of the first geographers to introduce the term *Culturgeographie* and an accompanying concept of cultural geography (as early as 1880). An important proof of this influence is the adoption of the concept of *Landschaft*, which Sauer took from German geography and then transformed it into his landscape concept, a central and meanwhile well-known feature of Sauerian geography.

Moreover, Sauer was influenced by American historical anthropology of his time. These and other influences led to the specific Sauerian strain of cultural geography where culture was the agent, space the medium, and the cultural landscape the result of human activities. According to Sauer, through time, culture influences and transforms space. Culture was thus regarded as the reason for the origins of certain landscapes.

Cultural geography conducted by Sauer and his followers of the Berkeley School circled around the whole array of human interventions and consequent transformations of the natural environment: domestication of plants and animals, the DIFFUSION of these domesticates, cultivation methods, and other artifacts of material culture and cultural practices, and their consequences for the transformation of the natural environment. These topics were studied from an explicitly ecological and rural, antiurban and perhaps antimodern perspective with a strong focus on folk and prehistoric cultures and native peoples. Geographical inquiry via observation, thus fieldwork and a critically distanced stance against theory and theorization of culture, was foundational in Sauerian cultural geography.

From the end of the 1970s on, however, Sauer's concept of culture was attacked by a new generation of cultural geographers. Representatives of this new school of thought (for example, Peter Jackson, James Duncan, and Denis Cosgrove are important representatives of the first generation of new cultural geographers) fiercely criticized Sauer and the Berkeley School. The traditional cultural geography was blamed for regarding culture as a fixed reality and, furthermore, for considering culture to be static and a superorganic entity. The critique went so far as to state that culture lowers individuals and human beings to the level of automates or Pavlovian dogs, who are passively forced

*The spread and use of the English language is one example of cultural geography. Linguistics and literary studies, communication theory, and the recognition of the construction of meaning through language are part of the academic study.*

into the dictatorship of culture. Drawing to a high degree on the findings of linguistic theory, and showing close affinity to critical social theory and the newly emerging field of Marxist-influenced British cultural studies, the new cultural geography developed a revised transdisciplinary concept of culture.

Arguing with constructivism and post-structuralism, culture was considered to have no ontological base, that is, to have no fixed reality. Instead, culture was considered to be the context for human action and interaction. Culture was seen as a set of relations that influence and, in part, determine how we live our lives. Multifaceted meanings and interpretations—in short, the plurality of cultures and heterogeneity of cultural processes—was emphasized.

Linguistics and literary studies, communication theory, and the recognition of the construction of meaning through language set the theoretical stage on which all material and nonmaterial facets of culture and also landscape were considered as “texts.” By way

of semiotic analysis, real and symbolic landscapes were interpreted in terms of symbolic content or the role for symbolic exchange. Different, multiple ways of seeing, experiencing and ascribing meaning to space were as much on the agenda of new cultural geography as was the role that cultural processes play in the construction of identities.

### COMPLEX SHIFTS

Furthermore, space theories fueled the new cultural geography’s view that landscapes, places, and spaces are under permanent social construction and transformation. These were the complex shifts in cultural geographic thinking after the cultural turn. With it, the ways of doing cultural geography had to be equally revised. As a consequence, the methodological focus of cultural geography changed, and it has become an increasingly empirical and interpretative subdiscipline drawing a great deal on discourse analyses and qualitative methods.

This shift in cultural geography was also fueled by questions for the social and political relevance of the subdiscipline. Matters of social justice, the concern with issues regarding ethnic minorities, subcultures, and “the other,” challenging fixed and essential notions of race or nation and gender and, furthermore, a concern with postcolonial and power-resistance issues were on the agenda.

### CULTURE WARS

The so-called culture wars on questions of dominance or on issues of the power of representation, as well as struggles over the power of the production of meaning, have been of special interest for cultural geographers. Space, culture, and power were the three points on which the canopy of new cultural geography was unfolded. To the same degree, cultural geography has been recognizing the importance of contemporary, urban, and popular culture (both production and reception), the practice of the everyday life, and the subjective experience and perception of space.

Moreover, there has been a growing concern for the workings of mass media on space or for the construction of space, and on various kinds of representations in television shows, film, literature, or music. From all this, it can be easily seen that a huge range of topics and issues entered the stage of cultural geographic research: film, books, food, music, advertising, religion, heritage, tourism, transnational networks and cultural transformations, sexuality, and so on have become the subjects of geographers' efforts to research matters of culture and the production of space.

### CRITIQUE OF NEW CULTURAL GEOGRAPHY

In recent years, however, there has been a considerable amount of critique of some aspects of how the new cultural geography has been practiced. This critique, put up for discussion by critical geographers with affiliations to Marxist and neo-Marxist thought (for example, Don Mitchell and Clive Barnett), basically considered new cultural geography as a victim of its own success. The critique is highlighting the dangers of a hegemony of the cultural, of the notion that “culture is everything,” and that in the doctrine of culturalism, nothing exists outside of cultural meaning. This culturalism, it is argued, weakens the political power of cultural geography.

A focus on everything that is in one way or another cultural is accompanied by a drift away from the study of exploitative economic systems of production. It is stated that although the focus on cultural politics is ex-

plicitly favored by new cultural geography, it is now in danger of being drowned by the mere number of all kinds of studies in new cultural geography. Often, it is argued, these studies are nothing more than a mere descriptive cataloguing of anything that is cultural, without explaining the complexity and multilayered characteristics of culture or cultural differences.

The accusation of arbitrariness of the themes and ways of doing new cultural geography has also been discussed. Moreover, it has been stated that a fast codification and a new orthodoxy of “the cultural” by new cultural geography has pushed away the radical character of the subdiscipline. Critical voices amplified the warning echo of a renewed version of culture as the superorganic entity of the Sauer era, which could be heard in the noise made through and around the new cultural geography.

The questions from these critical voices are connected to a plea for a thorough examination of the inner workings of culture—that is, of what culture is—and of the question about who reifies this culture—that is, what are the power relations, who oppresses, and who dominates and exploits in the realm connected to culture and its (re-)production?

Another point of critique regards the dematerialization of cultural research, that is, the turn away from the real needs and topics of the everyday toward the treating and reading of virtually everything as a more or less abstract cultural “text.” It is suggested that this might blunt the cutting political edge of cultural geography that is so urgently needed for the concrete improvement of the everyday life of people.

Nevertheless, as substantial as these critiques may be in showing actual and potential pitfalls of contemporary cultural geography, they can also be regarded as very valuable contributions for refining our understanding of culture and another step toward the reconsideration and further development of cultural geography.

## cyclones

CYCLONES ARE HAZARDOUS weather conditions distinguished by extreme blasts of wind moving in a circular pattern. Cyclones generally appear over tropical waters; however, some are able to reach land, where they inflict significant damage on buildings and communities.

Cyclones can be placed into categories such as hurricane (Western Hemisphere) and typhoon (Eastern Hemisphere). The categorization assigned to a cyclone is dependent upon where it originated. Wind speeds in cyclones can surpass 100 mi per hour (160 km per hour). Tropical cyclones with milder conditions are known as tropical storms.

Cyclones build over tropical seas. Heat gives cyclones their energy. Consequently, the ocean over which a cyclone forms must be warm. Other conditions required for a cyclone include a rapidly cooling atmosphere, a minimum of 300 mi (500 km) distance from the equator, and a slow vertical wind not exceeding 23 mi per hour (37 km per hour). This vertical wind is the product of differences between winds in the lower and upper portions of the atmosphere. The major contributor to the formation of a cyclone is a disturbance in the form of a thunderstorm or group of showers.

When all of these factors come together, conditions are right for a tropical cyclone. However, cyclones are spontaneous; a minute variation in one variable can be the difference between a hurricane and a thunderstorm.

Known as the “eye,” the circular area in the center of a cyclone has an environment quite different from the area it surrounds. Calmness and a light breeze characterize the eye. Temperatures and air pressure are normally higher, and the sky is generally very clear.

Strong cyclones can cause damage ranging from crop destruction to the total devastation of buildings, depending on the severity of the cyclone. Cyclones become most dangerous as they hit land and spawn tornadoes, which are formed when tropical cyclones begin to lose their power. The major variation between trop-

ical cyclones and tornadoes is their size. While the diameter of a tornado is measured in meters, the diameter of a tropical cyclone is measured in kilometers. One of the most destructive cyclone-spawned tornadoes in the United States caused around \$100 million worth of damage to the Austin, TEXAS, area in 1980.

Besides property damage, cyclones (and the ensuing tornadoes) cause death. Objects lifted from the path of the extreme wind are flung about as high-speed projectiles. In 1964, 22 people were killed by a tornado that hit the LOS ANGELES area in CALIFORNIA.

Meteorologists have come a long way in the forecasting of tropical cyclones. In their forecasts, they gather information from the global numerical weather prediction model, which is also used by many meteorological centers, to aid them in producing accurate warnings. The World Meteorological Organization has created Regional Specialized Meteorological Centers (RSMCs) that issue warnings to nations, which then issue warnings to the public.

Warnings are issued when a cyclone is likely to affect communities within 24 to 48 hours. The warnings include a forecast that predicts which communities may be affected, severity, movement, etc. depending on how severe a cyclone is, residents may be asked to take certain precautions or even evacuate the possible affected area.

### CATEGORY WARNINGS

Cyclones are divided into five categories determined by wind speeds, with category 5 being the worst cyclone of all. A category 1 warning is issued when wind gusts are less than 77 mi per hour (125 km per hour). A category 2 warning is issued when wind gusts are from 77 to 105 mi per hour (125 to 169 km per hour). When winds are from 106 to 139 mi per hour (170 to 224 km per hour), a category 3 warning is issued. Category 4 is when winds reach speeds from 140 to 173 mi per hour (225 to 279 km per hour). The most destructive of all is a category 5 cyclone with winds faster than 174 mi per hour (280 km per hour).

In order to avoid confusion when tracking the development of these storms, cyclones are regularly named. The naming of cyclones began during World War II when meteorologists in the U.S. armed forces unofficially named the cyclones giving them female names. During the early 1950s, tropical cyclones that formed in the North ATLANTIC OCEAN were named from the phonetic alphabet. In 1979 the U.S. National Weather Service used both male and female names. When an exceptional cyclone occurs, its name is taken

out of use to avoid confusion. More than one cyclone can occur at the same time, and if names are given, there is less confusion about which cyclone is being described. Cyclones can range from simple tropical storms to devastating hurricanes spinning at furious speeds. Their effects can be disastrous and long-lasting.

## Cyprus

**Map Page** 1121 **Area** 3,604 square mi (9,250 square km)  
**Population** 771,657 **Capital** Nicosia **Highest Point** 6,407 ft (1,951 m) **Lowest Point** 0 m  
**GDP per capita** \$15,000 (Greek) \$6,000 (Turkish)  
**Primary Natural Resources** copper, pyrites, asbestos.

CYPRUS IS AN island in the eastern MEDITERRANEAN SEA, 70 mi (113 km) south of TURKEY. For thousands of years, its civilization has been at the crossroads between Europe, Asia, and Africa. Today, Cypriots continue to play a role as a bridge between cultures, because of their island's proximity to the MIDDLE EAST, its cultural connections to GREECE, and its political status as one of the newest member states of the EUROPEAN UNION (EU).

Cyprus is politically divided, however, between the Greek-speaking majority in the southern part of the island and the self-proclaimed Turkish Republic of Northern Cyprus. This division has been in place since 1974 and remains unresolved despite pressure from the EU and the United Nations (UN).

The name *Cyprus* (Kypros in Greek) either derives from, or gives its name to one of the chief natural resources on the island: copper. This metal has been

mined from the Troödos range since prehistoric times. The Troödos dominate the central and southern part of the island. The rest of Cyprus consists of the northern Kyrenia range, or Girne in Turkish, and the plain between the two ranges, the Mesaoria. There are also scattered plains along the southern coast. The Kyrenia is a narrow limestone ridge that extends far to the northeast of the mainland to form the Karpaz Peninsula. The Mesaoria is semiarid, sheltered from rains by the northern mountains. Wheat and barley are grown there, but require IRRIGATION for agriculture.

Significant rivers rise from the Troödos Mountains but are mostly dry in the summer. Severe deforestation has contributed to the island's water problem, particularly around the city of Nicosia, which occupies the central part of the Mesaoria. Nearly 200,000 people live in this city, called Lefkosa by Turkish Cypriots, who claim the northern part of the city as their capital. Other cities include Limassol, Larnaca, Famagusta, Paphos, and the ruined city of Salamis.

The diversity of building styles in these cities reflects the varieties of outside influences that have dominated Cypriot history since the second millennium B.C.E. Cyprus was a Roman then a Byzantine province for 1,000 years until it was taken over by Crusaders in the 12th century, notably the de Lusignan family, who set up a Catholic kingdom in opposition to the majority Orthodox population.

Venetian merchants, eager to secure their monopoly on trade in the eastern Mediterranean, purchased the island in 1489 but lost it to the Ottoman Turks in 1570. The Turks ruled Cyprus through a restored traditional Orthodox hierarchy, reinforcing the position of the church and the Greek language in Cypriot politics and culture. In 1878, control of the island was ceded to the British, eager to safeguard their shipping lanes to the Suez Canal. Great Britain formally annexed Cyprus in 1914. Independence was granted in 1960, but the island remains a member of the British Commonwealth, and the UNITED KINGDOM retains sovereignty over two military bases on the south and southeast coasts.

As early as the 1820s, Greek Cypriots expressed a strong desire for political union, or *enosis*, with the rest of Greece. It is this desire that has been at the root of the tension between Greeks and Turks on Cyprus ever since. The original 1960 constitution allowed for minority representation in government, but these stipulations were dropped in 1963. In 1974, a coup backed by Greece prompted military intervention from Turkey, and the country was divided into the southern and

northern sections of today, divided by the so-called Green Line, patrolled by UN troops. In 1983 the Turkish area—roughly a third of the island declared itself to be the Turkish Republic of Northern Cyprus (TRNC), but it is recognized only by Turkey.

UN-led direct talks began in January 2002, and several proposals have been brought forward. A referendum on a plan set forth by UN Secretary-General Kofi Annan in April 2004 was approved by Turkish Cypriots but strongly rejected by the Greek population. It had been hoped that a settlement could be reached by the time of Cyprus's entry into the EU in May 2004. Many EU members were impressed, however, with Turkish willingness to settle their differences, which may in the long run lead to increased financial aid to the impoverished north.

The economy of Cyprus was severely disrupted by the division of 1974 but has recovered in the south, mostly through a huge increase in tourism. Tourism and other service industries today contribute 76 percent of the gross domestic product and employ 70 percent of the labor force. Millions of tourists per year come for Cyprus's clean waters and relatively undeveloped beaches. Southern Cyprus has also become a center for international business and offshore banking, due to its proximity to the Middle East, and its educated, English-speaking population. The north has had less of a recovery and continues to rely heavily on financial support from Turkey.

## Czech Republic

**Map Page** 1133 **Area** 30,450 square mi (78,866 square km) **Population** 10,249,216 **Capital** Prague **Highest Point** 5,256 ft (1,602 m) **Lowest Point** 377 ft (115 m) **GDP per capita** \$15,300 **Primary Natural Resources** graphite, coal, timber.

THE CZECH REPUBLIC consists of the two historic regions of Bohemia and Moravia. The Czech Republic borders SLOVAKIA to the southeast, POLAND to the north and northeast, GERMANY to the north and west, and AUSTRIA to the south. The Czech Republic is a parliamentary democracy with a parliament as its legislature. The prime minister serves as the head of government, and the president serves as head of state. Prague, Brno, Ostrava, and Plzen are major cities of the country.

Bohemia is a PLATEAU surrounded by the Ore or Erzgebirge Mountains and the Sudetes Mountains on the north and drained by the Vltava. Moravia is a lowland region that is drained by the Morava River, which flows into the DANUBE. The climate in the Czech Republic varies with the region from 30 degrees F (-1 degree C) in January to 67 degrees F (19.4 degrees C) in July. In higher elevations, the climate is colder and receives more rain.

The region comprising the Czech Republic was first settled by two Celtic groups, the Boii, from which the region Bohemia gets its name, and the Cotini. By the 5th century, Slavs from the east settled in the region and formed the kingdom of Bohemia in the 10th century. In the 15th century, Jan Hus led a movement against the Roman Catholic Church, which presaged the Protestant Reformation a century later. In 1526, the Habsburg dynasty from Austria gained control of the Bohemian throne.

The Thirty Years' War began in Prague when the Czechs rebelled against Habsburg rule in 1618. By 1620, Czech forces were defeated by the Habsburg forces, placing Bohemia under Austrian rule for 300 years. The convulsions of World War I led Czech leaders to push for full independence. In 1918, Czechoslovakia, with a diverse population of Czechs, Slovaks, Germans, and Ruthenians, emerged as a successor state to the Austro-Hungarian Empire. The First Republic of Czechoslovakia, led by Thomáš Masaryk, was organized as a Western democracy, which was one of the most stable and prosperous countries of Central Europe during the interwar period. During the 1930s, as Europe witnessed the rise of fascism, Czechoslovakia fell prey to Nazi ambitions.

In September 1938, at the Munich Conference, Britain and FRANCE gave the German-populated Sudetenland in northern Czechoslovakia to Adolf Hitler, who reorganized the country into the Second Republic in 1939 as a Nazi puppet state, granting autonomy to Slovakia.

Liberated by the Soviets in 1945, Czechoslovakia reemerged as an independent nation. By 1948, how-

ever, the communists, with the backing of the Soviet Union, took control of the government, creating the Third Republic. All prewar political parties were banned, and anticommunists were convicted in show trials.

The communists nationalized all industry, collectivized all agriculture, and restricted all churches in the years immediately following World War II. In 1968, President Alexander Dubcek proposed liberal reforms to the political and economic system, which included distancing Czechoslovakia from the Soviet Union. This “socialism with a human face” was put down by intervention by the Soviet Union and members of the Warsaw Pact, and Czechoslovakia was placed in a tighter orbit with Moscow. By 1989, pressures for change throughout Eastern and Central Europe led to the Velvet Revolution, which overthrew communist rule in Czechoslovakia. Dissident Vaclav Hável became president of Czechoslovakia and he oversaw its transition to democracy, with Vaclav Klaus as prime minister to oversee economic reform. The Velvet Revolution raised the age-old question of the relationship between the Czechs and the Slovaks, and by 1993 came the Velvet Divorce, which was the peaceful split of Czechoslovakia into the Czech Republic and SLOVAKIA. Since then,

the Czech Republic has made strides to integrate into the European economy. It has been one of the few Eastern and Central European states to make a successful transition to a free market economy, albeit with some difficulties in the rising inequality of wealth. The Czech Republic joined the NORTH ATLANTIC TREATY ORGANIZATION in 1999 and the EUROPEAN UNION in 2004.

Czechs make up the majority of the population of the Czech Republic. Sizable minorities of Slovaks and Roma (Gypsies) also reside in the Czech Republic. A significant German population existed in the Sudetenland, but many were expelled after World War II. The Czech Republic has had an industrialized economy since the days of the Austro-Hungarian Empire. Its chief exports are consumer goods, and machinery. Its chief industries are machinery, automobiles, textiles, and glass. Its imports are consumer goods and fuel.

## Damascus

DAMASCUS (in Arabic, “Dimashq”) is the capital and chief city of SYRIA, with a population of 1.7 million people (2002). The ancient city is also known in Arabic as “as-Sham” meaning “the Northern,” indicating its geographical position north of the traditional Arab homelands. Damascus is situated in the Ghutah Oasis on a plateau 2,263 ft (690 m) above sea level in southwestern Syria. The city is bisected by the Barada River, which separates the old city to the south from the newer, more modern city to the north. It lies just northeast of Mount Hermon (7,164 ft or 2,184 m), the highest point in the Anti-Lebanon Mountains that form part of Syria’s eastern border with neighboring LEBANON. To the east of the city lies the DESERT.

Damascus is only a two-hour drive from the MEDITERRANEAN coast, which is just beyond the Anti-Lebanon and Lebanon mountains to the east. Annual rainfall in the area ranges between 6 in (15 cm) and 7.87 in (20 cm), falling mainly between November and February. Although temperatures in the summer can exceed 104 degrees F (40 degrees C), the summer average is around 80.5 degrees F (27 degrees C) at the most. Winters are generally cold, averaging 41 degrees F (5 degrees C).

Damascus has been inhabited since prehistoric times and is considered by some to be the oldest con-

tinuously occupied city in the world. The first mention of Damascus is in Egyptian records, when the Pharaoh Thutmosis III conquered the city in the 15th century B.C.E. In 333 B.C.E., Damascus was conquered by one of Alexander’s lieutenants, who took it from the Persians. From 661 to 750 C.E., Damascus was the center of Islam and capital of the Great Omayyad Empire that stretched from Spain to India. In 1260 the city fell to the Mongols under Hulagu Khan, then fell again to the Mamluks following the Mongol withdrawal. In 1516, the city was captured by the Ottoman Sultan Salim I and remained part of the Ottoman Empire for the next four centuries. At the end of World War II, the city was freed from Ottoman control by an Arab contingent under the command of the British. Damascus became the capital of an independent Syria (from FRANCE) in 1941, although it did not officially take effect until 1946.

Damascus is made up of a sizeable old city, divided into the market area, the Muslim area, the Christian area and the Jewish area. The greatest part of the city, including the rectangular ancient city, is on the south bank of the Barada River, while the newer more modern suburbs lie to the north. Damascus has more than 200 mosques, but only 70 are still in use today. Of these, the Umayyad or Grand Mosque is the most famous, located just east of the Citadel and north of the Azem Palace in the old city. Damascus is famous for its

bazaars—streets lined with shops, stalls, and cafes. One such bazaar called “Street Straight” (in contrast to the typically narrow, crooked layout) is even mentioned in the Bible in connection with St. Paul’s conversion to Christianity.

Damascus has long been an important commercial center. In former times it was famous for dried fruit, wine, wool, linens, silks, and damask, a type of patterned fabric, named for the silk fabrics woven in Damascus. The city was also notable for the manufacture of damascened steel, the exceptionally hard and resilient steel used in making sword blades. Today the city is the trading center for figs, almonds, and other fruit produced in the surrounding region. Industries in Damascus include handicrafts, such as the weaving of silk cloth and the making of leather goods, filigreed gold and silver objects, and inlaid wooden, copper, and brass articles. Among the city’s other manufactures are processed textiles, metalware, refined sugar, glass, furniture, cement, leather goods, preserves, confections, and matches.

## Danube River

THE DANUBE RIVER IS the longest river in western Europe, surpassed in Europe as a whole only by the VOLGA in RUSSIA. Fourteen countries are drained by its watershed, covering over 312,000 square mi (800,000 square km): GERMANY, AUSTRIA (and small parts of eastern SWITZERLAND), the CZECH REPUBLIC, SLOVAKIA, HUNGARY (and a small corner of southwest UKRAINE), SLOVENIA, CROATIA, BOSNIA AND HERZEGOVINA, SERBIA AND MONTENEGRO, BULGARIA, ROMANIA, and MOLDOVA. The river travels 1,760 mi (2,850 km) from its source in Germany’s Black Forest to its large delta on the BLACK SEA, passing through some of the most beautiful and historic cities in Europe, including Vienna, Bu-

dapest, and Belgrade. The most famous stretch of the river, between Vienna and Budapest, has been immortalized numerous times in paintings, poetry, and music, notably Johann Strauss, Jr.’s “An der schönen, blauen Donau” (“On the Beautiful, Blue Danube”).

The Greeks called the Danube the “Ister,” the “Greatest of Rivers,” and for many centuries it was the border between the civilized Greco-Roman world and the Germanic barbarians to the north. Many centuries later, it formed the center, not the boundary, of the multiethnic Habsburg Empire, centered on Vienna and Budapest, which was torn apart by the peace settlements after World War I and by the Iron Curtain of the post-World War II era. There remains, however, some desire to reunite much of the region into a Danubian economic confederation, reflecting the reality that although language and culture divide Austrians, Hungarians, Serbs, Bulgarians and Romanians, the river unites them through commerce and industry.

The Danube starts in southwestern Germany, where it is called the Donau. Two small rivers, the Brege and the Brigach, come together at Donaueschingen, a town in the Black Forest. Its springs lie only a few meters from streams that flow westward into the Rhine watershed, thus ending up in the North Sea rather than the Black Sea, nearly 1,000 miles (3,000 km) apart. In fact, porous rocks in this area result in much of the water of the upper Danube actually seeping through the rocks to join the Rhine watershed, which has a lower elevation.

The river is too small for navigation as it winds through the Swabian Alps, passing castles and monasteries, and the ancient German cities of Ulm and Regensburg, once the capital of the Holy Roman Empire. At Passau, on the border with Austria, the Danube is joined by its first large tributary, the Inn. This was historically the western terminus of commercial river traffic, especially for grain coming to Central Europe from the plains of Hungary, but also for coal and iron ore from as far away as Russia.

In Upper Austria, the Danube passes some of the most famous baroque buildings in Europe, especially Melk, the Versailles of monasteries, perched on a hill above the river valley. Finally the river broadens into the famously smooth (and generally muddy brown, not blue) Danube as it passes by the capital cities of Vienna, Bratislava, and Budapest before turning south to cross the broad Hungarian Plain. This plain, the breadbasket of Central Europe, was also the site of many important battles, from the defeat and forced settling of the Hungarian people by Emperor Otto I in 955, to the

*The longest river in western Europe, the Danube passes through several capital cities, including Budapest, Bratislava, and Vienna. The river's watershed drains some 14 countries, from Germany to Bulgaria.*

destruction of the native Hungarian kingdom by the Turks at Mohács in 1526, and the defeat of Turkish forces after the siege of Vienna in 1683, finally halting their progress toward Central Europe.

South of this plain, the river again enters mountainous regions, guarded by the fortress city of Belgrade. In these middle reaches, the river (called Duna in Hungarian and Dunav in Serbian) receives its largest tributaries, the Tisza, which drains the eastern Hungarian Plain, the historic region of Transylvania (northwestern Romania), and southwestern Ukraine; and the Drava and Sava, which receive most of the waters of Slovenia, Croatia and Bosnia and Herzegovina.

### IRON GATES

In Serbia, the river's course meanders as it cuts passages through the confluence of the easternmost ALPS and the Carpathian Mountains. At its narrowest, the river passes through the Iron Gates, the site of one of Europe's largest hydroelectric projects, the Djerdap, which provides almost half of the electricity consumed by Serbia and Romania. The other major hydroelectric project on the Danube is the Gabčíkovo dam, in Slovakia. This dam, built in 1992, created a huge 11-mi (24

km) reservoir, with serious ecological consequences downstream in Hungary. Originally a partner in the project, Hungary withdrew with the fall of communism, causing severe tensions with the Slovak government. Other man-made projects along the river's course include the Rhein-Main-Donau Kanal, built in 1992, which links the North Sea to the Black Sea, though it is still mostly underused.

The lower course of the Danube forms the border between Bulgaria and Romania, through a broad drainage basin between the Carpathian and Balkan mountain ranges to the north and south. The river ends in a vast DELTA in Romania, the largest in Europe, with an area of 1,700 square mi (4,345 square km). Part of the delta also lies in the Ukraine. Flow at the mouth of the Danube averages 229,450 cubic ft (6,500 cubic m) per second, but has been recorded at 10 times this volume during high flooding. Some 122 million tons of sediment is discharged each year, creating one of the most extensive and fertile wetlands on Earth. Most of this is now protected by the Danube Delta Biosphere Reserve, 1.7 million acres (679,222 hectares) of marshes and lakes, declared a UNESCO World Heritage site in 1991.

The Romanian city of Galati, where the last major Danubian tributary, the Prut, enters the basin from Moldova to the north, is the river's chief port for oceangoing vessels, although it is 90 mi (145 km) from the Black Sea. Ships traverse the largest of the three main Danube channels (the Sfîntu Gheorghe) to enter the Black Sea, and thus to the Mediterranean. It is estimated that 100 million tons of cargo are transported each year on the Danube as a whole, underlying the economic importance of this waterway to much of Central and Eastern Europe.

## Danubian Gates

FOR CENTURIES, traffic along the DANUBE RIVER was hindered by a stretch of treacherous rocks and narrow gorges at the point at which the river cut through the Southern Carpathian mountain range. This stretch, about 62 mi (100 km) in length, along the border of ROMANIA and Yugoslavia (SERBIA), is known as the Danubian or Iron Gates, "Portile de Fier" in Romanian, and "Djerdap" in Serbian.

This barrier long formed a boundary between lower river commerce (to the BLACK SEA), and the river traffic of the upper Danube basin. The river flows through crystalline schists, limestones, and Sinaia strata (local Romanian stone), with both dangerous rock outcroppings in the riverbed, dangerous curves, and intense currents as the gorge reaches its narrowest points. The waters were most dangerous during low water periods (summer and autumn), and especially at night, when the height and verticality of the gorge walls allowed for extremely limited visibility.

Man added further dangers over the centuries, with nearly impregnable fortresses built by robber barons and extortionist princes. Most famous of these was the fortress Tri Kule, near Svinita, built by a Transylvanian prince to prevent Turkish infiltrations into the middle and upper Danube areas. But commerce continued. A

system of mule tracks and rope attachments were long in operation to drag boats through the area, and as the region freed itself from Turkish rule, several large channel-cutting projects were attempted, most notably by Serbia in 1890–98, with the construction of a series of canals between Virciorova and Gura Vaih, the most dangerous section of the gorges, which introduced the use of trains to pull boats upstream instead of mules. Other projects included the Sip Channel, underwater rock blasting, transverse and longitudinal embankments, beacons, signals, and so forth.

But along with this challenge of commercial transport, governments of the region realized the potential for hydropower also provided by such a concentration of water in a narrow space. More than two-thirds of the Danube basin as a whole lies above the Iron Gates, with a catchment area of 219,089 square mi (567,440 square km) from the Alpine, Dinaric, and Carpathian zones, producing an average flow of 194,936 cubic ft (5,520 cubic m) per second. The Iron Gates Navigational Authority was established in 1948 by Yugoslavia and Romania to examine both issues of facilitated transport and development of hydropower potential. In 1956, this body set out initial plans to build a "hydro-energetical navigational system." Work was begun in 1964, and full operation began in 1971. This remains the largest hydropower dam and reservoir system along the entire Danube, but as western institutions have begun to have closer access to the region, some wider issues have been raised, notably concerning the system's environmental impact, including upriver silting, downriver erosion, loss of animal habitat and worsening water quality.

## Darien Gap

STRADDLING THE BORDER of the republics of PANAMA and COLOMBIA, the Darien Gap is home to one of the least exploited and most diverse ecosystems in the world. Flanked by the PACIFIC OCEAN to the north

and west and the CARIBBEAN SEA to the east, the area includes two national parks, Darien National Park in Panama and Los Katios National Park in Colombia. The area is 30 mi or 50 km wide, from the North Pacific Ocean to the Caribbean Sea, and 54 mi or 84 km in length, when measuring from the terminus city of Yaviza in Panama to Lomas Aisadas in Colombia. The Darien Gap harbors varying landforms, from swamplands on the Colombian side to the mountainous rainforests with its tallest peak, Cerro Tacarcuna (standing at 5,535 ft or 1,845 m), on the Panamanian side. With more than 3 million acres of wilderness, the ecosystem found within is one of the most hotly contested, a political and environmental quagmire.

The Pan-American Highway, stretching approximately 16,000 miles or 26,000 km from ALASKA in the UNITED STATES to the Tierra del Fuego region of CHILE in South America, is broken only by the natural barrier of the Darien Gap. Initial plans to construct a road through the Darien Gap commenced in 1923 at the Fifth International Conference of American States. One of the primary reasons for the road is that through its completion, trade between North and Central America and South America would be more efficient with less reliance on the Panama Canal as the primary thoroughfare. Past opponents conferred that the spread of *aftosa*, or commonly known as foot-and-mouth disease, would possibly be spread from the cattle of Colombia to Central and North America if the road were built.

In 1991, the U.S. Department of Agriculture proclaimed this threat to be extinct. Road construction began in 1971 and lasted until 1974, when further construction was halted due to environmental concerns. During that time period, part of the area was officially put under protection through decree no. 84 for the Alto Darien Protection Forest. Since that time, the area was designated as a World Heritage Site as well as a United Nations-designated Man and Biosphere Reserve. The area is home to two major tribes and several smaller ones. The subsistence agricultural lifestyle of the Chocos (both Emberas and Vainanas) and the Kunas is threatened, as it will be a potential loss of their land and culture if the road through the Darien Gap comes to fruition.

The route has been fully surveyed and partially completed, yet the political, economic, and environmental issues surrounding its construction are the true barriers to its completion. The approximate costs for completion would be approximately \$200 million. Effective lobbying by environmental and indigenous

groups, costs associated with the road infrastructure, governmental bureaucracy, and the de facto control of the area by Colombian rebel groups have left the fate of the remaining 54 mi or 84 km of road in limbo. Widely publicized accounts of civilian kidnappings, drug-smuggling anarchy, and the controlling activities of Colombian rebel groups have made this area one of the most dangerous in the world.

## Davis, William M. (1850–1934)

WILLIAM DAVIS WAS among the leading geographers of the early part of the 20th century. Today, Davis might be more narrowly considered a geomorphologist based on his major research interests. But in his time, Davis enjoyed considerable influence over the direction and conduct of geographical science, in the UNITED STATES and in Europe.

Born to a prominent Philadelphia family—his maternal grandmother was the noted abolitionist Lucretia Mott—Davis was educated at the Lawrence Scientific School, Harvard University, in the 1860s, where he earned a baccalaureate degree and a masters degree from the short-lived school of mining engineering. Following a brief postgraduate period of world travel and employment at an observatory in the southern hemisphere, Davis began to teach at Harvard as an assistant to Nathaniel Southgate Shaler. In spite of an inauspicious start as an academic geologist and geographer, Davis mastered several scientific disciplines (meteorology, geology, and geography) and advanced at Harvard largely through attention to his publications and reputation. He held visiting positions abroad, most notably at the University of Berlin, and retired from an endowed chair at Harvard in 1912. Even so, Davis remained active in science well into the 1930s and with Ellsworth Huntington participated in several explorations, including those to the Pamirs and the Pumpelly Expeditions.

Although his contributions to science were many, Davis is best known for his “geographical cycle,” or

“cycle of erosion,” a sweeping theory devised to explain all geomorphological phenomena by means of a method he called “genetic description.”

According to the geographical cycle, all landforms will be reduced, through erosion, to peneplains, or near plains. To account for the observation that few landforms are peneplains, Davis argued that observed landforms may be explained by the processes that formed and continue to form them, by the structure of the underlying soil and rock, and by the stage in the advancement toward peneplanation that is observed in the present. Differing conditions of process, structure, and stage, Davis argued, can account for all observed variations in landforms.

The description of a landform according to these three criteria yielded a “genetic description,” a description that—because it accounted for the geographical genesis of the observed landform—also provided an explanation. In addition, Davis believed that variations in observed landforms were sufficiently few in number that they could be organized into a complete typology of ideal types.

The cycle of erosion had an American flavor to it in that it synthesized empirical work pursued, primarily, by geologists of the U.S. Geographical Survey in the late nineteenth century, among whom the best known are John Wesley Powell and Grove Karl Gilbert. At the height of his career, Davis’s primary interest was that European geographers, particularly leading German geographers, adopt the cycle of erosion. This was a campaign in which he was not altogether successful.

Davis was, by all accounts, an ambitious scientist. Moreover, his career coincided with the rise of doctoral programs in the sciences at American universities, and with the organization of American science into increasingly specialized disciplines and subdisciplines through scientific associations. He was a major participant in the creation of more than a dozen associations and served as president of both the Geological Society of America and the American Association of Geographers. His papers were published in the earliest volumes of a variety of journals, including *National Geographic* magazine, which he later abandoned when the journal veered from its initial intention to publish original research. At professional meetings and scientific conferences, Davis was well known for insisting upon high standards of research; his interventions in sessions occasionally bordered on bullying.

Following his death, Davis’s lingering influence on geography appeared to dwindle substantially, though interest in “Davisian” geomorphology reemerged by

the 1980s. In one area, however, Davis’s impact on geomorphology and in geology has been substantial and unabated. This influence is in the use of block diagrams and other diagrammatic techniques to present and summarize empirical research and scientific theory. Davis was, and remains, the undisputed master of the block diagram.

UNIVERSITY OF CALIFORNIA, SAN DIEGO

## Dead Sea

THE DEAD SEA IS a 390-square-mi (1,010-square-km) salt lake located on the borders of PALESTINE, ISRAEL, and JORDAN. It is the lowest water point in the world, and its coast, at 1,292 ft below sea level (-395 m), is the lowest dry point on Earth. The lake is divided into two unequal parts by el-Lisan or “the Tongue,” which is a wide peninsula jutting from the lake’s southeastern shore. The northern part is larger and deeper, reaching 1,300 ft (400 m) in depth. In contrast, the southern side reaches only 35 ft (11 m) and averages only 13 ft (4 m) in depth.

The Dead Sea formed when two plates of the Earth’s crust began spreading apart, creating a low region, the Rift Valley system, where the crust is stretched quite thin. The Dead Sea is located in the region where the Earth’s surface has sunk, and the lake’s bottom is still sinking, as much as 13 in (33 cm) annually, an incredibly fast rate. In contrast, on the eastern and western sides of the lake, looming mountains range from 2,500 to 4,000 ft (762 to 1219 m) in height. The Jordan River is on the lake’s north, and hills of solid salt (Jebel Usdum or Mount Sodom) rise up on its southern border. Lower than surrounding topography, the Dead Sea is fed over 6.5 million tons of fresh water by the Jordan River and smaller streams every single day. (It should be noted that large-scale Is-

raeli and Jordanian irrigation projects along the Jordan River have been causing the depth of the Dead Sea to decrease over the past 50 years; pollution is a concern.)

Because the lake has no outlets and is completely LANDLOCKED, the only way that water leaves is through evaporation; because the Dead Sea is located in a hot area with low precipitation, water evaporates to the degree that the sea level seldom fluctuates, other than because of irrigation, and what is left behind is the salt. Twenty-seven percent of the Dead Sea consists of solid substances, including sodium chloride, magnesium chloride, calcium chloride, potassium chloride and magnesium bromide. Potash, bromine, gypsum, salt and other products are commercially extracted from these waters, which become saltier as depth increases. At about 130 ft (40 m), there are approximately 300 grams of salt per kilogram of water, which is about 10 times the saltiness of typical ocean water.

Once the depth is greater than 300 ft (91 m), there are 332 grams of salt per kilogram, which is a state of saturation and explains the piles of salt found at the lake's bottom. Due to this extreme saltiness, the Dead Sea supports no plant, animal, or fish life. If a fish swims from a stream into this lake, it is instantly killed and then preserved by the lake's mineral salts. The only types of life, then, existing in the Dead Sea are microbes and highly specialized algae; on occasion, a seabird is seen resting on the lake's surface.

Humans can swim in Dead Sea waters, but because of the extraordinarily high salt concentration and density of the water, the experience is more like floating. When a person exits the lake, the body is coated with white salts, just as the shores of the Dead Sea are covered with this substance, and the person's skin can become irritated. The salts can irritate the eyes, and the water, if swallowed, tastes revolting because of the chloride of magnesium. Chloride of calcium gives the water its oily appearance.

The name *Dead Sea* is used in the Old Testament, although other biblical names are also listed for this body of water, including the Salt Sea, East Sea, Sea of the Plain, and Sodomitish Sea; the ancient cities of Sodom and Gomorrah were located at the lake's southwestern coast. Yet another name is the Lake of Asphalt, given because of the quantities of bitumen that rise to the surface of this lake, and current inhabitants call this body of water the Sea of Lot.

This region is famous for the Dead Sea Scrolls found in 11 caves in nearby Qumran from 1947 to 1956. Literally thousands of Biblical fragments and ancient Jewish documents were found, which added

greatly to the understanding of these religions. Today, the shores of the Dead Sea contain popular beaches, resorts, and spas.

## Deccan Plateau

LOCATED IN INDIA, in the southern part of the peninsula south of the Indo-Gangetic Plain, the Deccan Plateau can be considered the cultural and historical heart of India, defining the subcontinent. The great epic poems of the Vedas tell of the coming of the Aryan-speaking peoples that dominate all of northern India today. However, the very peoples they supplanted did not disappear but were concentrated in the Deccan and maintained distinctive cultures and language groups.

Remnants of a predominantly indigenous Dravidian culture (pre-Aryan) exist in the Tamil kingdoms found by the ancient Greeks. Tamil literature from 300 B.C.E. records the social life and academic accomplishments of these peoples. Three great Tamil dynasties emerged and challenged one another in internecine fighting. The rise of Buddhism in north India did reach into the Deccan, but the south remained resistant to the kings and Moguls that came in history's wake. Islam never made significant inroads into the Deccan Plateau. The coming of the Europeans from the 15th century onward gradually affected the coastal areas and even the interior Deccan gave way under the British raj (ruler). Characteristic of their distinct culture and history, many calls for independent states have arisen since the establishment of the Indian Union in 1947.

The Deccan Plateau is believed to be an ancient remnant of the Earth's original continent, Gondwanaland, which broke up to create the continents we know today. The plateau is a great ancient shield of basalt lava that now bears the scars of its long exposure to the

weathering effects of wind and water. The Vindhya Range marks the margins of the southern reaching peninsula and the Indo-Gangetic Plain. The Deccan is uplifted between 2,625 and 4,600 ft (800 and 1,400 m). The western Ghats increase in average height as they go south, reaching a maximum of 8,842 ft (2,695 m) in Kerala. The narrow coastal plain between the western Ghats and the ARABIAN SEA is marked by lagoons and backwaters. The plateau is primarily drained to the east with the headwaters of the Krishna, Bhima, and Godavari forming in the western Ghats and flowing up to 3,280 mi (1,000 km) eastward across the plateau to the BAY OF BENGAL. The eastern coastal plain is much broader and marked by the deltas of the Godavari, Mahanadi, and Kaveri rivers. The central Deccan is a series of smaller plateaus topped with rolling hills and dissected by many watercourses.

The monsoon cycle of dry and wet seasons affect the entire peninsula. The plateau has sparse but continuous dry deciduous forests across its southern third and along the eastern Ghats. To the north and in the central portions, the forest gives way to scrubland.

Over 300 million people live in the greater area of the Deccan Plateau. Sustainable resources such as forests and water are under increasing pressure. Deforested areas are being replanted with extensive monoculture that will further deplete the diversity of the ecosystem. Silting of reservoirs has been a historic problem and accelerated damming of water courses bodes ill for the long-term management of the various watersheds. Mining of the Deccan rich mineral deposits has not modernized. Techniques for the full recovery of the potential ore, management of overburden removal, and control of toxic wastes are all required.

## Delaware

DELAWARE IS ONE OF the Middle Atlantic states of the UNITED STATES. It is also the country's second small-

est state after RHODE ISLAND, covering 2,057 square mi (5,328 square km) within the DELMARVA PENINSULA. It is bordered by MARYLAND on the west and south, NEW JERSEY to the northeast across the Delaware Bay and Delaware River, and there is a short border with PENNSYLVANIA in the north. The state's 783,600 residents (2000) share their part of the peninsula with Eastern Shore Maryland and VIRGINIA. The area is part of the Atlantic Coastal Plain, which runs for more than 2,200 mi (3,667 km) from Cape Cod to the Gulf of Mexico. The countryside is relatively flat, with the land rising gently from sea level in the areas along the eastern shore to 442 ft (135 m) in the Piedmont region along the border with Pennsylvania. The southern part of the state is mostly swampland. A number of small rivers flow across the state, flowing either east to the Delaware (the Christina and Brandywine) or west across Maryland to the Chesapeake Bay (the Nanticoke). The state capitol is in Dover, although Wilmington is the largest city with 72,664 residents.

When Henry Hudson sailed into the Delaware Bay for the Dutch East India Company in 1609, he found the area of sand dunes, swamps, and gently rolling hills inhabited by Native Americans (Nanticoke and Minqua). Although both English and Dutch interests vied for the region, the Dutch established the first settlement in 1631. Within a year, however, that settlement was destroyed by a rare Native American attack. For the most part, the area's Native Americans were friendly and open to trade and within a short time several Dutchman interested in settling the area received permission to colonize the area for Sweden. Peter Minuit, one of the more notable of the early settlers, led the expedition for the Swedes, organizing New Sweden and founding Fort Christina on the site of today's Wilmington in 1638. Following a number of battles among the English, Dutch, and Swedes, the area was finally turned over to England in 1674, where it remained until the American Revolution. The Colony of Delaware became a state in 1776 and was the first state to ratify the new Constitution of the United States in 1787.

By the end of the 18th century industry was making inroads in Delaware. In the Piedmont region of the north with the rolling wooded hills, the Brandywine and Christina rivers provided ideal locations for gristmills to grind grain into flour. At the same time, Wilmington became a center for the manufacture of cloth, paper, and flour products, an industrial sector that flourished into the 19th century. The Du Pont family established a gunpowder mill on the Brandywine River

in 1802, marking the beginning of what would become one of America's most successful family business empires.

More recently, the finance and insurance sectors have become increasingly significant employment and income generators, although manufacturing and agriculture are still important. The manufacturing, credit card, banking, and insurance industries are heavily concentrated in the north. Broiler chickens, soybeans, corn, and dairy products comprise the heart of a still vibrant agricultural sector, utilizing lands generally below the Chesapeake and Delaware Canal in the south. Potatoes and other vegetables are also grown; in addition there is a small fishing industry centered on harvests of clams, menhaden, oysters, and scup.

Because Delaware has some of the more lenient laws regulating business taxation and practice, the state is home to many of the largest corporations in the United States. This is especially true for those in the banking and financial services sectors, and these now dominate the state's economy. The chemicals and materials monopoly that was founded by the Du Pont family in the 19th century, despite being broken up by the government in an antitrust suit in 1912 and losing another suit in the 1950s over the firm's major interest in General Motors, continues to be one of the largest corporations in the world. In addition to chemicals and chemical products, the biomedical, apparel, processed foods, rubber and plastic products, and transportation equipment industries are important and contribute to the state's wealth.

Clay Reed, *The Delaware Colony* (Crowell-Collier Press, 1970); Michael Schuman, *Delaware* (Benchmark Books, 2000); U.S. Census Bureau, [www.census.gov](http://www.census.gov) (August 2004).

RICHARD W. DAWSON  
CHINA AGRICULTURAL UNIVERSITY

## Delmarva Peninsula

THE 5,940-square-mi (15,384 square km) Delmarva Peninsula is located in the mid-Atlantic area of the UNITED STATES and borders the Chesapeake Bay, the Delaware Bay and the ATLANTIC OCEAN. The historic importance of the area is that it formed an important political and social demarcation between the North

and the South of the United States: the Mason Dixon Line.

The border between MARYLAND and DELAWARE formed the initial portion of the Mason-Dixon line, drawn in the mid-1700s to settle a boundary dispute between the Calvert family and the Penn family. The Mason-Dixon line later became the delineation between northern states and southern states, and therefore between slave states and free states. The name Delmarva comes from letters in the state names that share it, including all of DELaware, and portions of MARYland, and Virginia.

Compared to the rest of the United States, the Delmarva Peninsula is strikingly flat, with most of the area approximately 30 ft (9 km) above sea level. Interestingly, this area was not always flat. Two hundred million years ago, the APPALACHIAN MOUNTAINS were the edge of the ocean. The shoreline itself then was rocky, resembling a steeper version of the current coast of MAINE. The long, flat, sandy beaches that characterize today's Delmarva coastline emerged because of continental drift. The Appalachians have been moving westward for 245 million years, and they've been doing it at a yearly rate that just about equals the speed at which fingernails grow. As the Appalachians were drifting westward, they also eroded. Their rocks were weathered into sand. This sand was carried by streams and rivers to the coast and deposited. Over time, these deposits, once under water, have been exposed and now form the coastal beaches.

### CHANGING GEOGRAPHY

Today, coastal currents and storms are changing the geography again. This can be seen even in maps of the area between the coastal towns of Rehoboth and Cape Henlopen. These show that since 1878, the shoreline has moved almost 1,200 ft (366 m) inland. The wide sandy beaches of Delmarva are a major tourist destination and a major economic resource for the area. Maryland's heavily developed Ocean City has a year-round population of less than 10,000, but during peak summer weekends, the population swells to more than 300,000.

With a shallow and changing coastline and a lack of natural harbors and energy resources, Delmarva did not become heavily industrialized as did some of its neighboring areas. Today, intensive truck gardening agriculture, poultry farming, and the seafood industries form the backbone of the peninsula's economy. Its strategic location, just a few hours from Baltimore, Washington, D.C., and Philadelphia, with overnight

access to almost one-third of the nation's population, have made it a major food supplier for the East Coast of the United States.

## delta

A DELTA IS AN AREA of land that has been built up at the mouth of a river, where it flows into a quiet body of water, such as a lake or an ocean. The delta is formed when the river, which is moving swiftly and carrying sediment such as mud, slows down to enter the larger body of water. At the slower speed, the water can't carry as much sediment, so most of it is dropped onto the bottom of the ocean. It builds up layer by layer, over a long period of time, until it is above the surface of the water.

The delta builds up at the end of the river itself, since it cannot rise higher than the surface of the ocean. As more and more sediment is deposited, the delta grows in size and extends further upstream. The more mud the river carries, the faster a delta will build up. Most deltas have a roughly triangular shape. The name came from the Greek letter delta, which is shaped like a triangle. If plants grow on the delta, their roots and remains become part of the soil, enriching it. A delta is an ever-changing landform. If the original channel of the river is filled with sediment, the stream will overflow across the surface of the delta, dividing into smaller streams or channels called distributaries.

The size and shape of the delta depends on several factors. If the waves are strong where the river enters the ocean, any deposits will be washed away and a delta will not form. The weaker the waves in the ocean at that point, the more the delta will build up. Delta formation is also dependent upon the amount of material being carried by the river. If waves are not very strong, the delta will grow rapidly, with long fingers of land building up along the distributaries. This is called a bird's-foot delta.

Throughout history, deltas have been important to civilizations. The soil of a delta is usually very fertile and is good for farming. Delta lands often flood every year, spreading another layer of silt. Many deltas have unhealthful climates and poor drainage, but still tend to support dense populations of people. All over the world, deltas have influenced the lives of people. Some of the most important deltas include the MISSISSIPPI RIVER delta, the NILE RIVER delta, and the delta of the GANGES river.

The Mississippi River delta is located at the southern edge of the UNITED STATES, where the Mississippi River empties into the Gulf of Mexico. South of New Orleans, LOUISIANA, a bird's-foot delta has built up. The resulting valley provides habitat for many species of plants and animals important to the ecology of the area. Farms on the delta produce much of the country's supply of soybeans, rice, sugarcane, and cotton. The Mississippi River still deposits sediment on the delta. In some places, more than 98 ft (30 m) have been deposited in the last 100 years.

The Nile delta is located at the northern end of the Nile River, where it flows into the MEDITERRANEAN SEA in EGYPT. The Nile is the longest river in the world. Most of the delta's surface is covered with crops, contrasting sharply with the barren desert around it. Cairo, the capital of EGYPT, is an example of a delta supporting a dense population. The city has a population of more than 11 million people, which is more than 26,000 people per .386 square mi (1 square km). At its widest, the delta is about 153 mi (250 km) wide along the Mediterranean.

The Ganges-Brahmaputra delta was created by sediments deposited by these two great rivers in the area of BANGLADESH. People have built their homes on artificially raised earthen hills to protect them from the yearly floods. Like the Nile delta, this region is overpopulated. Population density far exceeds 500 people per .386 square mi (1 square km). Over 300,000 people were killed by floods there in 1991. Farming is almost the sole occupation on this delta.

## demographics

DEMOGRAPHY IS THE study of populations (a term used to denote the collection of persons alive at a particular point in time and who meet certain criteria). Demographics have to do with population statistics. Usually referred to as a census, most often these data are collected through a survey process and by public agencies at all levels of government or non-governmental organizations. These data include variables representing vital economic and social statistics. They generally include race, age, gender, religious affiliation, educational levels, income levels, and housing and employment information. They also include information about population density, which is the number of people per square mile, as well as how the total population and population subgroups are distributed throughout a selected geographical area. The information collected by agencies may include data on death and birth rates, life expectancy, and health problems, to name a few. When linked to basic demographic data, researchers can better understand links between these variables; for instance: the life expectancy of American males who are of Hispanic ethnicity and have yearly incomes below \$18,000.

Most countries have a formal census process that attempts to count every member of the population and to collect information about that person and his or her household. All of this individual data is then aggregated (combined) and sorted by variables to inform us about the people in a particular area. For most of Europe, census taking dates back to the 16th century. The founding fathers of the UNITED STATES recognized the value of collecting population data and ensured that the process would be funded and protected by the U.S. Constitution.

The U.S. Census Bureau conducts a census every 10 years. In addition to taking a “head count,” each individual is asked to identify sex, age, relationship status, race, whether or not of Hispanic origin, and housing tenure and ownership status. Approximately 15 percent of the population is selected randomly to receive a longer survey from which additional demographic information is collected. These additional demographic data include marital status, place of birth, citizenship and year of entry, ancestry, place of residence five years ago, language spoken at home, veteran status, disability information, present labor force status including industry, occupation, and class, place of work and journey to work, previous year’s work status, and previous year’s income. Housing data, which are socioeco-

nomics indicators, are also collected. Statisticians also use equations to make assumptions about the U.S. population at different levels of geography (local, state, country) and cross-reference socioeconomic data with demographic data to create population profiles. The smallest census geography is a “block.” It represents approximately 150 people and gives a very detailed picture of the people who comprise a small area while protecting each individual’s right to privacy.

Developing countries also recognize the need for population counts and surveys but are often impeded by resources, political strife, and massive shifts in population resulting from civil war, famine, etc. These countries are aided by organizations like the United Nations in collecting important demographic data to aid economic development and stability through resource management.

The process of collecting demographic data is becoming more complex as the world’s population increases and many countries, such as the United States, become more heterogeneous and mobile. As a result, understanding demographics has also become more complicated because many individuals no longer fit neatly into one particular race or ethnicity category. Further complicating the process in all countries is the fact that many census takers and demographic researchers are challenged by accuracy problems resulting from community and individual reluctance to report personal information.

Demographic data provides students, researchers, and decision makers with information that is essential to understanding our world. It allows us to identify social groups, shifts in populations through migration and immigration, relationships between people and geography (cities, states, countries, world regions, and the world as a whole), as well as relationships between people, political boundaries, and resources. Demographics have a wide scope of applications. For example, private industries might use census data and market research for product development, targeted advertisement of services and products, and selecting new markets/locations for business development.

Demographics also play a vital role in how government dollars are allocated. Some of these decisions are linked to total population numbers, while others are linked to particular demographics such as age, race, gender, income, or a combination of these. Additionally, nonprofit organizations might use demographic data to improve service delivery by targeting geographic areas with assumed specific needs based upon the area’s demographic profile.

Demographic data not only provide information about today, they also help us establish population trends that can help predict and prepare for the future. Newer demographic changes make it difficult to measure and understand the sources for that change until more data is collected over time. An example: in 2000, the U.S. Census Bureau began collecting information about grandparents serving as caregivers; the true scope of this demographic shift will not be measurable until the same data is collected again in 2010. Likewise, some changes have been gradually occurring over a longer periods of time and substantial data have been accumulated for examination. These data and changes allow researchers to use statistical modeling to project future population trends and make recommendations for preparation and response. By doing so, decision-makers such as politicians and organizational leaders have information to guide them in allocating resources to plan for future need and demand on resources.

Population growth tends to be very imbalanced between rich developed countries and poorer developing and third world countries. Countries in Asia and Africa have large population numbers of people under the age of 15, whereas countries in North America and Europe have fewer young people and rapidly aging populations. These basic statistics indicate very different demographic futures as well as different demands on resources. A younger population will require more schools and job training, whereas an older population will require increased geriatric programs and services to respond to long-term health problems that result from aging. Governments and agencies can use this information to plan for these needs. Private sector businesses can also use these projections for business development.

Population change at all geographical levels will eventually affect economic consumption, social and political relationships, and environmental outcomes to name just a few of the impacts. Without demographics, many decisions about natural and monetary resources would be random, and it would be difficult to project long-term impacts to allow better use of the world's and countries' limited resources.

### VISUALIZING DEMOGRAPHICS

Demographics are inextricably linked to geography. As a result of the internet, we can easily access data about the world's population as a whole or by region, a country's population, a state's population, or a city's population. Sophisticated mapping software, such as geographic information systems (GIS), provides the

technology to link demographic data to their respective locations. By examining demographics and linking them to place, we learn a lot about the available labor force, the need for age-appropriate services (such as day care or day programs for the elderly), and we can make assumptions about quality-of-life issues. For example, an area populated with people with moderate incomes and college educations will likely have better quality of life, through access to resources, than areas with high poverty and low education rates. Many demographic data have been mapped and made available to the public. These maps allow us to see patterns that may not be obvious when looking at numbers.

## Denmark

**Map Page** 1130 **Area** 16,807 square mi (43,094 square km) **Population** 5,384,384 **Capital** Copenhagen **Highest Point** 571 ft (173 m) **Lowest Point** -23 ft (-7 m) **GDP per capita** \$29,000 **Primary Natural Resources** petroleum, natural gas, fish, salt.

DENMARK IS A COUNTRY whose history and culture is almost entirely shaped by the sea. With a coastline of 4,535 mi (7,314 km), nearly 500 islands, and numerous fjords and inlets, nowhere in Denmark is more than 31 mi (50 km) from the sea.

The Danes have traditionally played a role as a bridge between the language, culture, and politics of Central Europe and the Nordic nations of Scandinavia.

Denmark is the smallest of the Nordic countries but has frequently been the dominant member, with the highest population and strongest economy.

Denmark consists of the peninsula of Jutland, connected to northern GERMANY through the province of Slesvig, plus the main island of Zealand (Sjælland), which includes the capital of Copenhagen and nearly half the population and a number of smaller islands. Most of these islands are clustered in an archipelago to the east of Jutland, in the southwest corner of the Baltic Sea: Fyn, Lolland, Falster, and Møn. Other islands, generally long and thin, lie off the west coast. These are the northern Frisian islands, including Fanø and Rømø.

The island of Bornholm lies about 80 mi (130 km) to the east in the Baltic Sea, a relic of a time when Denmark's kings completely controlled the Baltic. This control was due to the strategic placement of Denmark along the narrow series of straits that connect the Baltic to the North Sea: the Skagerrak, the Kattegat, and the Øresund. The Øresund in particular is only about 12.4 mi (20 km) wide, and until the 17th century, Denmark controlled both shores, effectively controlling all shipping access in and out of the Baltic Sea. Today, the eastern shore of the Øresund is part of SWEDEN, and since the completion of the monumental Øresund bridge and tunnel system in 1999, it has become more a connector between the two countries.

Jutland is almost entirely flat, particularly along the western coast, where dikes are necessary in some places to keep out the sea. Some areas in the center are hilly, but the average elevation is only 98 ft (30 m). Much of this landscape shows the effects of glaciation through several ice ages: morainic hills, moors, and downs.

Several fjords indent the peninsula, notably Flensborg Fjord, which divides Denmark from Germany, the Åbenrå and Vohle fjords of the eastern coast, and the Lim Fjord, which slices nearly all the way through the tip of northern Jutland—with the creation of the Thyborøn Canal, this section of Jutland became, in fact, an island.

Denmark's largest city and major port is Copenhagen (population 1.4 million) on Zealand. Other major ports include Esbjerg, Ålborg, and Århus on Jutland. Other large cities are on the islands: Odense on Fyn (home of Hans Christian Andersen), Nykøbing on Falster, and Roskilde and Frederiksberg on Zealand. Lacking significant raw materials, Denmark made use instead of its position as a seafaring nation to import, process, and re-export products, creating one of the

*Boats at Nyhaven in Denmark illustrate the character of the country as inextricably linked to the sea.*

most dynamic economies in Europe. Its commercial fleet is the third-largest in the world, and its standard of living is among the highest. Most of the country remains, nevertheless, a largely agricultural country, and some of Denmark's chief exports are meat and dairy, in addition to the more high-tech pharmaceuticals and electronics and the world-famous Lego toys. Denmark joined the EUROPEAN UNION in 1973 but has resisted full integration into the economic union, opting out of the common currency in 2000. The Kingdom of Denmark also includes GREENLAND and the FAEROE ISLANDS, both of which have developed near total autonomy in internal matters since the 1970s.

## desert

THERE IS A TENDENCY, in popular opinion and some public policy, to view deserts dismissively as unproductive wastelands. The 14th edition of the *Encyclopaedia Britannica* made the case with exuberant eloquence: "Desert, a term popularly applied to any environmentally extreme, deserted, desolate, uninhabitable waste area." While they are indeed less productive of biomass than other land areas at comparable altitudes and latitudes, deserts and their unique environmental characteristics have long interested physical geographers and ecologists. And while deserts do appear inhospitable, most have long histories and prehistories of human habitation and resourceful human adaptation to desert landscapes. Deserts account for a substantial fraction of the Earth's total land area, occurring in every continent but Europe and dominating northern Africa, Asia Minor, and central and western Australia.

The defining characteristic of a desert is a mean annual precipitation of 10 in (24 cm) or less. Climatologists refine this definition, however, by contrasting mean annual precipitation to rates of evaporation and transpiration, or water lost by plants. Ecologists may further stress adaptations of desert plants and animals to varying conditions of aridity over time. Although the climate of ANTARCTICA fits the climatological definition of a desert, and while it is so considered by some geographers, the special characteristics of the continent are generally excluded from discussions of desert geography and ecologies. The term is applied almost exclusively to land areas, but comparisons to comparably underproductive areas of open ocean can make for worthwhile ecological discussions.

Even if Antarctica is excluded, the global distribution of deserts is quite diverse. Deserts occur at tropical and temporal latitudes, centered on the Tropics of Cancer and Capricorn. Little of the land area at the equator (the exception is the HORN OF AFRICA) is desert. The greatest continuous land area of the world's deserts is

found in a band stretching along the TROPIC OF CANCER from the North Atlantic across Africa and continuing through Asia Minor and into regions of KAZAKHSTAN, northeast of the CASPIAN SEA. While most deserts abut oceans along a portion of their boundaries, a small number, including the GOBI DESERT, are LANDLOCKED.

Two climatological factors tend to create conditions of aridity and hyperaridity (very high ratios of evaporation and transpiration, or evapotranspiration, to precipitation). One factor is global atmospheric circulation, augmented by cold ocean currents: Most deserts are found in "horse latitudes," around 30 degrees latitude, and along the western coasts of continents. Under such conditions, air warmed near the equator circulates aloft to the north and south, cooling, sinking, and compressing as it reaches the higher latitudes. Deserts also occur on the leeward side of mountain ranges, where a "rain shadow" forms as air movement over mountains cools and condenses moisture in the air on the windward side, thus drying the air that passes to the lee.

Although the aridity of deserts is often associated with high surface temperatures, some of the world's deserts occur in regions of lower mean annual surface temperatures. These latter are therefore known as cold deserts.

Among the geomorphological features found in deserts, the best known are sand dunes. Dunes are not found exclusively in desert regions, however; they are products of eolian (wind-driven) processes that can occur under a variety of conditions. Even so, the bulk of the world's sand dunes are found in deserts. Geomorphologists classify dunes according to forms that arise in response to the supply of sand, the persistence of wind direction and speed, and the presence or absence of stabilizing vegetation. Steady winds, very low vegetation, and moderate sand supplies create barchans, dunes having a crescentic shape as viewed from aloft.

Rocky plateaus and plains formed from alluvium with little soil development are more universally typical of desert landscapes. In the deserts of North America, these occur in regions that have been extensively deformed by normal faulting, uplifting alternating blocks of crust relative to others. The resulting basin and range (or graben and horst) structure is characteristic. Basins become loaded with sediments that have eroded from adjacent ranges. Due to low precipitation and therefore low rates of sediment transport, sediments tend to be sorted with finer grains collecting at the centers of basins (known as bolsons), coarser grains

Although the world's deserts are less productive than other land areas at comparable altitudes and latitudes, their unique environmental characteristics include long histories and prehistories of human habitation.

at the margins, and the coarsest grains or talus found in the bajada, at the boundary between a plain and the uplifted pediment. The remains of an intermittent or relict lake at the center of a basin are called a PLAYA.

Soil development in desert regions is generally poor. Organic material is sparse, and aridity promotes preservation rather than decomposition. Under some conditions, especially in basin and range landscapes, sediments are reworked chemically, resulting in accumulations of soluble minerals such as gypsum and calcium carbonate. High concentrations of calcium carbonate can cement alluvium at the surface in caliche, or desert pavement.

In spite of the inauspicious conditions for life that obtain in desert regions, thousands of species of organisms have evolved to survive and even to thrive under such conditions. Typical adaptations in desert plants, for instance, include means to reduce transpiration and tissues adapted to store water against periods of drought. There is no one strategy for coping with arid conditions; some plants have taproots to reach down into sources of groundwater, while others have radial systems of roots close to the surface to maximize absorption when rain falls.

Humans have long inhabited, traversed, and found refuge in desert regions throughout the world, deriving sustenance by hunting and gathering, through agricultural practices that include but do not necessarily require irrigation, and as nomadic pastoralists. Growing and stratified or stratifying societies have emphasized agriculture, constructing IRRIGATION networks in many of the world's deserts to support sustained and reliable yields. Efforts to irrigate desert lands have tended to be limited in longevity because of the high rate of evaporation in desert climates, which results in an aggregation of minerals, unhealthy for plant life.

UNIVERSITY OF CALIFORNIA, SAN DIEGO

## desertification

SINCE THE mid-1970s, the United Nations (UN) has considered desertification a significant environmental problem involving high economic, societal, and human costs. The UN's Conference on Desertification, held in 1977, outlined an action plan over a 20-year period that, unfortunately, did little to change the course of desertification.

The definition of desertification itself is controversial. In 1991, the UN Environment Program defined it as "land degradation in arid, semi-arid, and dry sub-humid areas, resulting mainly from adverse human impact." In 1992, the UN convened the Conference on Environment and Development (UNCED) to draw up formal measures that included setting up a Committee on Desertification to review reduction of greenhouse gas emissions, preserving biodiversity, and protecting international waters.

The official draft of the UNCED report expanded the definition of desertification to: "land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors including climatic variations and human activities."

The World Bank defines desertification as "a process of sustained decline of the biological productivity of arid and semiarid land; the end result is desert of skeletal soil that is irrecoverable [sic]. Common indicators include a reduction in the amount of diversity of plant and animal species, loss of water-retention capacity, lessened soil fertility, and increasing wind and water erosion."

The key issue in desertification is the presence of climate variation, as experts point out that the more important dimension of the problem refers not to the expansion of existing deserts, but to the result of human activity in dry land masses, as land is exploited and inappropriately managed. Desertification is not only intrusion by sand dunes; it is gradual loss of soil fertility from excessive cultivation or grazing, destruction of trees and shrubs for firewood, and the lack of effective water resource management.

Desertification can happen through natural causes in any climate zone. The areas at risk are mainly in Africa, but also extend to Asia and the Americas, including the western portion of the continental United States. The expansion of such vast deserts as the SAHARA, GOBI, and the Arabian are not the main concern, scientists say. Rather, areas that are gradually drying out, making the practice of farming progressively unsustainable, are becoming sources of global ecological

and human concern. In marginal areas, where natural resources are depleted over time and the land becomes unproductive, starvation may ensue.

### 1 BILLION PEOPLE AFFECTED

The UN reports that, currently, desertification affects about 8.9 billion acres (3.6 billion hectares) or 70 percent of all "dry" lands across the globe. That is nearly one-fourth of the total land area on Earth, affecting about one sixth of the world's population. Over one billion people all over the world are affected by drought and desertification. Populations in these areas occupy about one-fourth of our planet and face major catastrophes as a result of such climate change, including deterioration of vulnerable land, and eventually chronic food insecurity and starvation.

As desertification takes hold, farmers give up trying to grow crops and move to cities in search of work. Cities are then faced with deciding how to deal with resulting overpopulation and lack of sufficient food resources. The ultimate consequences of desertification include economic loss, poverty, famine, human suffering, and widespread death. Strategies to deal with desertification address poverty, land ownership, and social structures. Because large regions generally suffer an inability to maintain adequate standards of living for their population when desertification occurs, the expanding loss of productive lands has a domino effect, bringing down entire communities.

Naturally occurring processes formed deserts over long periods of time, and over time, most deserts have grown and shrunk, irrespective of human intervention. In many cases, desert edges may become more humid than dry, making it harder to define a desert border. These areas maintain very fragile ecosystems because of different climates. Small hollows may support vegetation that insulates heat and protects the area from winds, and these vegetated areas may be cooler than their surroundings, resulting in various microclimates. If humans are involved in using these areas for farming, for example, they may stress the ecosystem beyond its capacity, resulting in more degradation of the land.

Overpopulation and resulting excessive cultivation and grazing leads to falling soil fertility and lesser crop growth. Exposed topsoil is further eroded by the elements and is conducive to surface runoff and erosion. Eventually, this vicious cycle results in destruction of crops and more infertile land.

Overgrazing is a significant factor in land destruction that causes a decline in vegetation including grasses; excessive grazing results in the replacement of

perennial grass species with species of forbs (weeds) that do not hold soil as efficiently as grass does. Soil is also compacted by livestock trampling near watering holes, and dunes are overrun and destabilized after relatively short periods of grazing time. These cumulative processes cause a significant decline in the health of the very animals that depend on the land for sustenance, as well as the often permanent and irreversible result of desertification.

### REDUCING DESERTIFICATION

The UN has identified various strategies to reduce further land erosion. Early warning systems and knowledge of water resource management techniques assist communities to maintain the integrity of land. Careful land and livestock management is essential to preserve fertile ground, and the use of special seeding techniques over sand dunes can manage vegetation. Narrow strip planting and reforestation of new species and varieties that can tolerate extreme weather conditions are other effective ways to regenerate crops and native flora. Sheltering of native plants is important in maintaining ecological balance, so “social forestry,” a process in which villagers take responsibility for forests that surround their village, is a method of empowering those directly impacted by the degradation of productivity.

Global awareness is essential in understanding the magnitude of desertification. Unlike other catastrophic natural disasters—such as CYCLONES, for instance—desertification happens over a long period of time; it is thus easier for communities to overlook its effects and adjust to the status quo. As such adaptation exacerbates the social effects of desertification, governments need to take the lead in preparing communities to deal with the problem.

The UN’s Convention to Combat Desertification Treaty, ratified in 1996, is intended to promote effective local programs and international partnerships to combat the problem globally. The World Bank has also cooperated in the global effort to stem the destruction of land by deploying and mobilizing its resources in concert with global needs. Education, focusing especially on local and international actions that threaten landmass, is needed to develop positive changes that can result in increased food security and amounts of land available for food production.

Desertification is not an easily solved problem for a government and its people. It is difficult for citizens to understand that they must be more responsive to land use issues. Countries that may not be directly affected should take into consideration the global seriousness of

desertification and take steps to alleviate its effects and prevent its expansion. Desertification causes increased flows of refugees, which affect all countries because migration almost certainly ensues when a land region cannot sustain its native population. Countries are often forced to take on fleeing immigrants, and other countries find themselves having to commit scarce financial resources to combat—or help other nations combat—the catastrophic effects of desertification. Desertification is a global problem with devastating results for planet Earth.

## determinism

DETERMINISM (from the Latin *determino*, meaning “define”) is a basic philosophical theory about general interdependence and interconditionality of phenomena and processes. This idea was explained for the first time in ancient natural philosophy (atomistic ideas, peripathetic school), in notions about primary origins and elements. Later, it was developed by Persian poet Omar Khayyam, Italian naturalist G. Bruno, and others who believed in the existence of cause and effect as a rational consequence.

Laplace’s determinism is the first attempt to generalize and theoretically interpret general deterministic ideas, proposed by Pierre-Simon, Marquise de Laplace, the 18th-century naturalist and philosopher. According to his variant of determinism (sometimes called strict

or mechanistic determinism), everything in the contemporary world (and the human being itself, taken as a biological and social creature) is completely caused by previous facts and events. He believed that the unidirectional and dynamic connections of any phenomenon's states could be described with the help of laws of physics and mechanics.

According to Laplace, the universe is utterly rational, and complete knowledge of any given situation permits us to experience with certainty the future and the past of any unit.

### **GEOGRAPHICAL DETERMINISM**

As a particular form of strict deterministic theory, geographical determinism approves geographic environment as the principal determinant of social layout and cultural development. As early as at the middle of 4th century B.C.E., it had been designed as a specific direction of philosophic thought, with at least two extreme schools: one of climatic psychology and one of climatic ethnology. Later, climatic astrology originated.

The Enlightenment and modern ideology reconsidered these ideas in a framework of establishing general regularities in livelihood systems, social spheres, and political organization. During the 20th century, geographic determinism was associated mainly with theories trying to explain the unevenness of social and cultural development of separate countries and peoples exclusively by peculiarities of their natural habitat. Today, geographic space influences political decision making and is the subject of scientific modeling of geopolitics, which is regarded as a special discipline, formed on the border of anthropogeography, political geography, and political science.

### **MARXIST DETERMINISM**

Marxist determinism emphasizes total objectivity, interdependence, and interconditionality of objects, facts, and phenomena of the real world. Apart from causal interrelations, Marxist determinism presumes the existence of a wide spectrum of interconnections of different kinds, such as spatial and chronological correlation, functional dependence, symmetry connection, system elements interaction, mutual determination of part and the whole, connection of states in development and movement, and so on.

In such contexts, social regularities define the mainstream of historical process but do not determine the whole diversity of individual and group activity. So freedom in purpose formulation is ascribed to the human being and to the social group as well.

Economic determinism stresses economic primacy in relation to other form of social practice. In its Marxist variant, the economy is regarded as a sphere of human activity that determines (or, at least, influences decisively) the character and essence of political and social processes. On this basis, society's historical development could be conceptualized through the series of socioeconomic formations (primitive, slavery, feudal, capitalistic, and communist). In such a context, state, ideology, politics, and culture are regarded as expressions of economics, which, in its turn, reflects the interests of the dominative class and results from the mode of production. In a broader sense, economic determinism implies that political and social infrastructures are conditioned by the character of the economy.

### **STATISTIC AND SYSTEM DETERMINISM**

The 20th century brought new insight to deterministic ideas thanks to the origin of statistic and probabilistic methods of scientific research. As a result, statistic regularities (instead of total and exhaustive causality) were revealed and conceptualized in the framework of a wide spectrum of probabilistic world theories.

Statistic determinism is widespread, mainly in the context of sociology, demography, and other social sciences. It presumes that in large sets of social phenomena, one can trace statistic regularity or the general tendency of development. In such a context, character of social connection is interpreted as possibilistic and regular at the same time.

System determinism (or determinism revealed in the framework of theory of system) implicates the integrity of elements forming the social system and acts as a some kind of basis of these elements' peculiarities and their changes in time and space.

Both system and statistic determinism don't deny the role of conscious and targeted human activity. They pay special attention to the mode by which the main purpose of such activity is formulated. Into the 21st century, deterministic ideas are withstanding indeterminism, which denies the existence of objective causal regularities.

## Dhaka

DHAKA BECAME the capital of the newly formed sovereign state of BANGLADESH in 1971. The city has a tropical monsoon climate with heavy summer rainfall (June through September), about 80 in (203 cm) annually. Summer is hot and humid and winter is dry and mild.

It is located on a tributary of the Meghna-GANGES river system and was founded by the Hindu Sena kings in the 7th century C.E. After a Delhi-based Muslim Sultan's conquest of Bengal, Dhaka remained a regional capital between 1203 to 1764. After the British conquest of Bengal in 1757, Dhaka became a secondary capital as Kolkata (Calcutta) became the capital of both Bengal and British India. As a result of the partition of South Asia in 1947, the present-day Bangladesh became a province of PAKISTAN (from 1947 to 1971) and Dhaka again was relegated to a provincial capital.

National capital status in 1971 turned Dhaka into a fast-growing dynamic metropolis. From a population base of 104,000 in 1901, and 239,000 in 1941, Dhaka has grown to 12.5 million in 2000, making it the primate city of the country, and 9th most populous metropolis of the world. The very congested and badly maintained old city, heart of the commercial center, has given rise to a typical traditional bazaar city center. Dhaka is one of the most homogeneous cities, as 95 percent of its population speak Bengali and 90 percent are Muslims.

Because of their number, Dhaka is designated as the City of Mosques. Its long history bears architectural imprints from Hindu, Muslim, British, and post-independence periods. A third of modern Dhaka's population live in dire poverty and in slums, though the rich have built buildings of brick and mortar. Dhaka's problems are many: A preponderance of mosquitoes, high level of noise pollution, flooding after heavy rains, jammed streets with three-wheelers, buses, motorbikes, cycle-rickshaws, and pedestrians.

Dhaka prepared a metropolitan plan in 1995 based on a modern approach. This plan addressed "residential provisions of middle and upper income groups, industrial and commercial development and intra-city transportation." The proposed flood abatement efforts include construction of huge retention ponds on the eastern and western fringes of the city. The problem of enacting the plan is a lack of funding.

## diffusion

DIFFUSION IS the spread of a phenomenon, such as an idea, a technological innovation, or a disease, over space and time. The origins of interest in diffusion in geography can be traced back to the work of the German geographer Frederick Ratzel (1844–1904). In the second volume of his highly influential *Anthropogeographie*, Ratzel described the diffusion of cultural traits. This work laid the foundation for the studies by geographers on cultural history, which came to be most influential in the work of Carl SAUER (1889–1975) and the geography department at the University of California, Berkeley, from the 1930s through the 1950s, which is referred to as the Berkeley School.

Sauer (1952) argued that issues of cultural diffusion should be one of the main concerns of geography. Sauer believed that the diffusion of ideas, such as agriculture, from "cultural hearths" (cultural centers) has been one of the main driving forces in human history. The research undertaken by the Berkeley School also influenced the study of the origin and spread of culture in the 1960s and, more recently, the study of environmentalism and the processes of cultural globalization.

Another key geographer in ideas of diffusion was the Swede Torsten Hägarstrand (1916–2004). His 1952 doctoral dissertation on innovation diffusion as a spatial process had limited impact until its publication in English in 1967. Hägarstrand observed that the diffusion process can be likened to a wave pattern that loses its strength as it moves away from its source of origin.

Hägarstrand provided a mathematical basis for simulating innovation diffusion on the basis of probability although it is rare for diffusion to be completely random. Each location is regarded as having a different set of probabilities for diffusion based on a mean information field that structures the way in which diffusion flows through a region. Four different types of diffusion are usually recognized.

In expansion diffusion (also referred to as contagious diffusion), a phenomenon, such as knowledge of

an innovation or a disease, is spread by direct contact or word of mouth. This type of diffusion exhibits the frictional effects of distance by which those furthest away are less likely to receive this information than those closer to the initial source (distance decay).

A more developed model of the simple epidemic model of contagious diffusion in which all members of a population are regarded as susceptible to a disease is the General Epidemic Model. In this approach a three-fold division of the population is made into susceptibles, infectives and removals (infectives who after a period of time either cease to pass a disease on to others or communicate information regarding an innovation). The General Epidemic Model has been utilized to study a number of different types of diffusion with respect to disease and the dispersal of plants and animals and has also been refined to introduce greater complexity into studying transmission.

The third type of diffusion is termed hierarchical. In this case diffusion can leap over intervening people and places. Hierarchical diffusion helps explain diffusion within large bureaucratic systems such as multinational firms. It is also a useful way to explain diffusion in the fashion industry, where innovations may originate in fashion centers such as PARIS, NEW YORK, or Melbourne, then diffuse to chain stores in larger cities and from there to retail stores in smaller towns.

The fourth type of diffusion is relocation. In relocation diffusion, information (or plants and animals) moves along with the people who know it. Once relocated, migrants will often then spread innovations via an expansion diffusion process. Indeed, the different types of diffusion are usually occurring almost simultaneously.

Absolute or absorbing barriers are a feature or condition that completely prevent diffusion, for example, mountain ranges that prevent population dispersal. However, over time barriers may become permeable because of technological advances or changes in perception, such as the Appalachians with respect to European settlement in the United States. Finally, there are reflective barriers that deflect an innovation wave back on itself, such as in the case of human settlement on a coastline.

Substantial research continues to be done on diffusion in geography with respect to innovation particularly with respect to technology and products. In this there is a strong relationship to research on time geography as well as trying to understand the social processes behind individual adoption and resistance to adoption.

## direction

**DIRECTION IS DEFINED** as the line or course on which something is moving, or at which it is aimed to move, or toward which something is pointing or facing. Direction is commonly referenced as an angle made by a given line with an axis of reference, that is up, down, right, left, and so on. With geographic direction, the reference system employed is usually the latitude-longitude coordinate system with meridians converging on the North and South Poles and lines of latitude running parallel to the equator.

The compass rose is the most common graphical representation of the directional angles referenced to the LATITUDE-longitude coordinate system. The compass rose has appeared on maps since the 1300s and it was originally intended to represent the directions of the winds. The compass rose gradually became the standard representation for expressing the orientation of maps and the directions on those maps. The compass rose comprises several sets of directional cues, and each of these has an associated angle, starting with north and increasing in a clockwise direction. First among these cues are the four cardinal directions—north, south, east, and west—with north having an angular measure of 0 degrees, east represented as 90 degrees, south as 180 degrees, and finally west as 270 degrees.

The second set of directional cues is known as the primary intercardinal points, which are (in clockwise order) northeast, southeast, southwest, and northwest. The associated angles for these points are 45, 135, 225, and 315 degrees, respectively. Primary cardinal points are always named with north or south first, then with east or west depending on which two points are bisected. Lastly, the set of secondary intercardinal points (north-northeast, east-northeast, east-southeast, south-

southeast, south-southwest, west-southwest, west-northwest, and north-northwest) bisects the cardinal directions and the primary intercardinal points. Secondary intercardinal points are always named by the nearest cardinal point first, then with the nearest primary intercardinal point. When angles are used to specify direction, this is termed the *azimuth system of direction*, and when cardinal and intercardinal points are used, this is termed the *bearing system of direction*.

With the acceptance of the compass rose and its associated angles as a standardized means of specifying direction, interest turned to determining direction from a point (or between points) on the earth's surface. There are numerous ways to determine direction including using shadow measurements of the sun to determine the north-south line, recording the position of the setting sun on the vernal and autumnal equinoxes (due west), locating the star Polaris (North Star), which is within 1 degree of the North Pole, or similarly using the Southern Cross in the Southern Hemisphere, and using a nautical almanac that records celestial positions for every hour of the year, among other methods. When in the field, a magnetic compass is most often used for determining direction relative to magnetic north. Magnetic north and geographic (or true) north differ slightly, and therefore navigation based on a magnetic compass must correct for this variation. This can be done with the aid of a map that includes a declination diagram illustrating the local difference between magnetic and true north.

One of the distortions caused by projecting a curved surface (the Earth) onto a flat surface (a printed map), is a distortion of directions. If the purpose of the map is to aid in the determination of direction, a map PROJECTION that preserves this property must be chosen.

The problem of finding accurate directions is clearly of great importance in navigation, but direction can play an important role in social processes as well. As one example, consider that many religions have historically placed importance on the direction of prayer. If a worshipper wishes to face toward a particular place (such as Mecca in Islamic religious tradition) this direction should be determined by using a map that preserves direction between Mecca and the location of the worshipper.

## distance

EMPLOYING THE GEOGRAPHIC sense of the term, *distance* can be defined as the amount of separation between two points or objects on the surface of the Earth. Geographic distance is usually expressed as a linear measurement between locations using one of several commonly accepted metrics (a metric is a standard of measurement using associated units).

Historical distance metrics were often based on the lengths of human body parts. Among these was the cubit, defined as the distance from the tip of the elbow to the end of the middle finger, and the foot (whose corporal association is obvious). These measuring instruments were extraordinarily useful in that they were always available and could not be misplaced. Unfortunately such metrics differed based on the size of person making the measurements, sometimes by several inches or more.

Although attempts at standardizing distance metrics have appeared throughout history, only a few have persisted in wide use to the present day. One of these originated with King Edward I of England when he commissioned the Iron Ulna, or master yardstick, in the early 14th century. One-third of the yard was decreed to be a foot, and one-36th was termed the inch. This system of linear measurement has persisted as two related systems: the British Imperial System and the U.S. Customary System. In the U.S. Customary System the yard is the base unit while a rod equals 5.5 yards, a furlong equals 220 yards, and a mile equals 1,760 yards. The distances related to the depth of bodies of water are often given in fathoms, each fathom being equivalent to 2 yards. The UNITED STATES is the only major country widely employing this system for linear measurement, and efforts have been made to replace it with the more widely accepted metric system.

The metric system became standardized in the late 18th century in France when several proposals were made for defining the standard length of a meter. The successful proposal used the size of the Earth as the ultimate standard of measurement. More specifically, a meter was defined as one ten-millionth of the distance

between the North Pole and the equator along a meridian traveling through Paris. Although error associated with making this measurement (due to miscalculations of the shape of the Earth) resulted in the standard meter being slightly shorter than it ought to be given its definition, this distance became the standard nevertheless. A prototype bar of platinum-iridium was constructed as the standard meter and was kept at standard atmospheric pressure to avoid changes in its length. A subsequent definition of the meter was made based on the length of the path traveled by light in a vacuum over a very small fraction of a second. With the meter established as the basis for the metric system of linear measurement other units were computed as decimal ratios of the meter. The metric system is now the most widely used system of measurement and is more accurately termed the International System of Units (SI).

Given that there are several well-accepted units for linear measure, one can use these metrics to determine geographic distances. In many cases, a geographic distance to be measured is small enough that the curvature of the earth does not alter the measurement within the precision capabilities of the measuring instruments being used.

When this is true, one can assume that the surface on which the measurement is being made is a plane, and the calculation of distance between two points can be made using the Pythagorean theorem. ( $a^2 + b^2 = c^2$ ) where  $a$  and  $b$  are the lengths of two sides of a right triangle, and  $c$  is the length of the hypotenuse of that triangle. If the two points are given by pairs of coordinates ( $x_1, y_1$ ) and ( $x_2, y_2$ ), then  $a^2 = (x_1 - x_2)^2$  and  $b^2 = (y_1 - y_2)^2$ . Solving for the value of  $c$  allows one to calculate the straight line distance between the two points across the plane.

When longer distances across the surface of the earth are being measured, one must compute the spherical distance between the locations. Spherical distance calculations consider that the distances across the surface of a curved object (like the Earth) are longer than the planar distance between points.

## Djibouti

**Map Page** 1114 **Area** 8,958 square mi (23,000 square km) **Population** 457,130 (2003) **Capital** Djibouti **Highest Point** Musa Ali 6,653 ft (2,028 m) **Lowest Point** -550 ft (-168 m) **GDP per capita** \$1,400 **Primary Natural Resources** negligible.

BORDERED BY ETHIOPIA, ERITREA, and SOMALIA in Africa, the country of Djibouti (the former French Somaliland and then AFARS and Issas) is the epitome of a geopolitical state. It is a state that has been created and defined by its geographic location. Similar to GIBRALTAR and Aden, Djibouti controls access and egress from a major waterway: the Suez Canal and RED SEA. From 1862, Djibouti was controlled by the French, especially the French Foreign Legion, until 1977. In 2002, the UNITED STATES established a military base here. Were it not for its geopolitical value, there would be no economy beyond herding of goats and no political unit.

Small in area, with some features such as Lake Assal below sea level (550 ft or 168 m), Djibouti is arid and occupied primarily by pastoralists and refugees from the war between Ethiopia and Eritrea. Its deep harbor and the fact that all traffic to and from the Suez Canal (and thus Mediterranean Europe) must pass its location has made the area important far beyond any local resources—of which there virtually are none to speak of.

The only natural resource, other than its location, is the salt deposit at Lake Assal. However, salt is more easily and cheaply obtained in many other areas. The closest local parallel to the geopolitical value of Djibouti would be Aden, which also controls access to the BAB AL MANDEB, Red Sea and Suez Canal, but Aden was controlled by the British.

Djibouti also is located on a major fault (fracture) zone known as AFAR (for Africa/Arabia), where major geologic plates are separating and rotating, making it an extremely active earthquake and volcanic area as well.

## Dominica

**Map Page** 1137 **Area** 294 square mi (754 square km) **Population** 69,655 **Capital** Roseau **Highest Point** Morne Diablatins 4,775 ft (1,447 m) **Lowest Point** 0 m **GDP per capita** \$5,400 **Primary Natural Resources** timber, hydropower.

THE LAST OF THE islands of the West Indies to be colonized, chiefly because of the fierce resistance of the native Carib population, the island of Dominica now retains the only pre-Columbian population in the eastern CARIBBEAN SEA. Dominica also maintains more of its original tropical vegetation, due to the roughness of its terrain—it is 66 percent forested, compared to 36 percent on SAINT VINCENT, and only 9 percent on GRENADA. The inability to establish large plantations thus served to preserve Dominica's natural riches, a fact that is now a blessing to the country's economy as a chief draw for tourism, supplemented by reserves of timber for export.

As with the other islands in the Windward group of the Antilles, Dominica is volcanic in origin. Morne Diablatins is the island's highest volcanic peak, but there is also considerable thermal activity and a large crater lake located only 7 mi (11 km) from the capital city of Roseau. The Caribs (approximately 3,000 in number) live mostly in a reservation set up for them in the northeastern part of the island. Many still farm small plots and are involved in weaving traditional baskets used all over the island and sold to tourists. Having richer and more luxuriant soil than its neighbors, Dominica grows most tropical products with ease but specializes in limes.

The island, named by Christopher Columbus on Sunday (Domingo), November 3, 1493, lies between the French departments of GUADELOUPE and MARTINIQUE and was itself a French colony until 1763. Among those many North American and Caribbean

territories reassigned to the British by the Treaty of Paris, Dominica remained a British colony until independence in 1978.

Because of Carib resistance and the steepness of its volcanic slopes, Dominica was not developed as a major sugar producer like its neighbors. Small farmers continued to live much as they had done before the British takeover, and the island retains much of its French flavor, especially in its patois. Possibly as a result of this duality of loyalties, Dominica has chosen to become a republic while remaining a member of the British Commonwealth—in other words, unlike ANTIGUA or SAINT KITTS, the chief executive of Dominica is an elected president, not the hereditary British monarch. With one of the lowest per capita incomes in the Lesser Antilles, the population is increasingly young and urban, with nearly a third living in the capital of Roseau.

## Dominican Republic

**Map Page** 1137 **Area** 20,729 square mi (48,730 square km) **Population** 8,715,602 **Capital** Santo Domingo **Highest Point** 10,416 ft (3,175 m) **Lowest Point** 151 ft (46 m) **GDP per capita** \$6,300 (2002) **Primary Natural Resources** nickel, gold, silver.

THE DOMINICAN REPUBLIC, which sits on the western portion of the island of Hispaniola in the CARIBBEAN SEA, was once covered with lush rainforests full of thousands of flora and fauna species throughout its steep mountains and deep valleys. However, this country has faced hundreds of years of deforestation, and many of the swamps were drained. Because of its

tropical maritime climate, frequent rainstorms send topsoil into the ocean, and a barren landscape has been created. The top soil deposits in the ocean have also destroyed marine coral reefs. But portions of the countryside have retained their beauty with different trees and over 218 bird species. In the surrounding waters, humpback whales gather, and sea turtles, manatees, and pilot whales dominate the marine life.

The island of Hispaniola was founded by Christopher Columbus in 1492 and ultimately became a permanent Spanish settlement. After years of oppression and unrest, an independent Dominican Republic was created in 1844. For 25 years after independence, the Dominican Republic was ravaged in a leadership conflict between General Pedro Santana and General Buenaventura Báez and their armies. In 1882, General Ulysses Heureux rose to power and, until his assassination in 1899, mismanaged the nation's affairs. He violently repressed any opponents and poorly managed the economy. By the end of the 19th century, the Dominican Republic's economy had progressed to an agriculturally driven one. Tobacco and coffee became two of the main crops.

After Heureux's death, the sugar industry was revived and American businessmen began to invest in the plantations. In 1916, U.S. military forces were sent to the Dominican Republic. For eight years, these forces occupied the country, disbanded the Dominican army, and remodeled the legal system. The military also trained local militias. By 1924, the American military had left the Dominican Republic with Raphael Leonidas Trujillo in charge of the army. Six years later, Trujillo gained complete power of the government.

Trujillo enforced a very repressive dictatorship. His followers wreaked havoc against political opponents, even reverting to assassinations. However, he maintained positive relations with the UNITED STATES, by offering favorable conditions to American companies, and not supporting communism. However, in the 1950s, Trujillo's power base slowly began to crumble, and his relations with the United States suffered. One year after being connected to an assassination attempt against the Venezuelan president, Trujillo himself was assassinated. For the following four years, the Dominican Republic teetered on the edge of a socialist state.

In 1965, President Lyndon B. Johnson called on the U.S. military to once again enter the country, and restore order. One year later, Dr. Joachim Ballaguer, a former Trujillo lieutenant, was elected president in an allegedly corrupt election. He remained in power for 12 years, and then after a tumultuous election was re-

placed by Antonio Guzmán of the Dominican Revolutionary Party.

In 1982, Guzmán committed suicide and was replaced by Salvadore Blanco. However, corruption led to his downfall and eventual imprisonment. Ballaguer was again voted in to office in 1986. A public works reconstruction program was implemented, but by 1988, the country suffered a two-year recession. In June 1989, massive demonstrations were held in protest of the economic difficulties and lack of basic resources such as water and electricity.

Balaguer instituted a second series of economic reforms, which included balancing the budget and limiting inflation. These measures were overall successful, and economic growth continued through the decade. In June 1996, Leonel Fernandez Reyna was elected president. He continued the economic reforms but was not reelected in 2000. Hipólito Mejía from the Revolutionary Democratic Party was voted in as president. The economic reforms continue in the country and the country is slowly beginning to prosper.

## domino theory

THE DOMINO THEORY states that if one vital country in a region falls to an expansionist negative philosophy, then other countries in the region similarly situated and similarly structured would fall victim to the same philosophy, either through force or through influence of example. In its pure form, the negative philosophy is communism but in variants it can be socialism or theocratic Islam. The theory was used as a rationale for American interventions, including most disastrously the intervention in the Vietnam War.

After World War II, the geopolitical situation of an already shaky alliance between the Western capitalist democracies and the communist Union of Soviet Socialist Republics fell apart as the Soviets sought to establish a buffer zone of satellite states and the UNITED

STATES asserted the rights of all nations to independence in a postcolonial world. Each side accused the other of starting the Cold War, and the world quickly polarized as each camp took an “either against us or with us” attitude and enforced it through alliances, such as the Soviet bloc Warsaw Pact and the U.S.-led NORTH ATLANTIC TREATY ORGANIZATION (NATO). Battling monoliths faced each other across the Iron Curtain in a Cold War where none was allowed to be neutral.

The West definitely feared communism, as it had since the Russian Revolution had generated Red Berlin and America’s red scare back in the aftermath of World War I. The communists had been active in the intervening years, notably in SPAIN, and there were examples where briefly democratic countries became communist as the map of Europe turned “red” after World War II. The U.S. consensus was that all communist movements were part of the communist international, puppets of the Kremlin. Communism was a monolith, not an idea, like democracy, that might arise in a nation independently of either the United States or the Soviet Union.

Because the Soviets had managed to acquire territorial control in East GERMANY, POLAND, CZECHOSLOVAKIA, ROMANIA, and BULGARIA and because communists were in power in Yugoslavia and CHINA, the United States perceived the other side as a monolith united into a single bullet aimed at the Western heart. RUSSIA had been toppling dominoes from the first day after the gunfire of World War II stopped. The only alternative was to contain communism where it existed and keep it from entering any other territory, be it free or non-aligned (a shaky category of potential candidates for coming under the American umbrella).

Presidents Harry Truman and Dwight Eisenhower both subscribed to the idea that the only way to confront Russia was to keep it penned where it was. The successful prevention of the Greek domino’s fall was validation. In 1947, GREECE was at risk, with communists in position to take another country into the opposing camp. American involvement halted the collapse, saving Greece for the West. That was containment.

According to the theorists, containment of communism outside of Greece kept neighboring TURKEY from falling into the Soviet sphere. Had Turkey fallen, then the Soviets would be able to influence the MIDDLE EAST, with Asia next. A corollary to containment was the domino theory.

Liberal and conservative alike in an age of consensus about the evils of communism subscribed to the

domino theory. They agreed that if the communists ever managed to take one country, then that country’s neighbors would fall one by one until none was left to the free world. This communist imperialism was what President Eisenhower referred to in April 1954 when discussing Indochina and the domino theory.

In response to a question from Robert Richards from Copley Press about the strategic importance of Indochina to the free world, Eisenhower replied that the region had a significant value as producer of raw materials the free world needed—tin, tungsten, and rubber. Also, it was undesirable to have another population fall under a dictatorship after the loss of 450 million already. Most important, there was the “falling domino” principle. Set a row of dominoes up properly, touch the first one, and watch them fall one by one until none is left standing. Even the last one is toppled. Lose Indochina, and next would be Burma, THAILAND, the Malay Peninsula, and INDONESIA. Eisenhower further explained that these losses would alter the defensive geography of the region. Not only would JAPAN, TAIWAN, and the PHILIPPINES be vulnerable, but so would AUSTRALIA and NEW ZEALAND. It would also put pressure on Japan, having lost its commercial sphere, to turn toward the newly communized countries.

The domino theory was the rationale for U.S. support for colonialist FRANCE and later dictatorial governments of South VIETNAM in Indochina against what it read as a communist insurgency compounded by a communist invasion. In a 1963 press conference, President John Kennedy expanded the domino theory to LAOS. He explained that Laos, a country of 2 million, was a sovereign state whose people desired to be independent. It also had a strategically vital border on the MEKONG RIVER. If it were to go communist, it would imperil the northern frontier of Thailand, would increase pressure on CAMBODIA, and would increase pressure on Vietnam, which would increase pressure on Malaya. The other side understood the domino theory and would possibly seek to take advantage of the vulnerable dominoes one after the other. It was vital to uphold the Geneva Accords, to protect the dominoes to preserve the stability of Southeast Asia.

The theory acquired critics over time, but it remained the majority view as the United States entered deeper and deeper into the war in Indochina: Vietnam, Laos, Cambodia. From Eisenhower’s blocking of the elections in Vietnam when he expected the communists to win, to Kennedy’s sending of “advisors,” to Johnson’s escalation until well over half a million American troops were fighting to save the South Vietnamese

domino, to Richard Nixon's secret plan for peace, the domino theory kept the U.S. in Vietnam. For more than a decade the dominoes held. Then the United States retreated, leaving Vietnam to solve its problems alone. The south went communist.

After the Democratic Republic of Vietnam came into being as the unified successor to the divided country, in 1975 Laos and Cambodia also became communist. This apparent falling of dominoes to the communists validated the theory for some. Those who denied the legitimacy of the domino theory argued that the examples were not valid, because North Vietnam had long dominated Laos and that the "domino" had already fallen. In Cambodia the Khmer Rouge regarded Vietnam as an enemy. Although they shared a loose philosophical tie, there was no monolithic communism there. If anything, there was a potential fracture in the monolith, a counterforce to the dominant communist power, as China and Yugoslavia had been for the Soviet Union.

President Richard Nixon's perspective was that the most compelling argument for the theory was that the dominoes had faith in it. It's true that countries bordering communist ones did fear subversion. That was one of the justifications for the treaty system: mutual protection of the potentially endangered dominoes.

A variant on the domino theory espoused by Noam Chomsky is that the capitalists feared a successful unaligned socialist state because it would provide an example of an alternative path to the communist or capitalist ones. It would cause others to fall like dominoes into the socialist neutralist pattern. Chomsky cites this fear as the primary reason that the United States intervenes in politically and strategically insignificant parts of the world such as GUATEMALA, ANGOLA, and EAST TIMOR. The counter to this theory is that it fails to fully account for Soviet influence in the third world.

Although few of the original supporters of the theory still subscribe to it, some still justify military activism using the domino theory. Rather than communism, in the post-Cold War world, the threat is Islamic theocracy and the counterweight is liberal democracy in the Middle East. The theory applied during the Iran-Iraq War as a rationale for taking the side of IRAQ in order to prevent IRAN from spreading its radical theocracy in the Middle East. The neoconservative rationale for invading Iraq in 2003 was that toppling Saddam Hussein would create a model liberal democracy that would spread the same system through a tumbling of repressive autocratic regimes from Iran to SAUDI ARABIA, perhaps throughout the Muslim world.

And there remain those who believe that the Vietnam War validated the theory. According to this logic, the countries of the Association of Southeast Asian Nations (Philippines, Indonesia, MALAYSIA, SINGAPORE, and Thailand) were free because the United States gave them the example that it would support regimes that resisted communism. The Indonesians evicted the Soviets in 1966 because the United States was fighting for freedom, theirs included, in Vietnam. That resistance halted an inevitable advance of communism to the Malacca Straits and Singapore.

Another domino theory deals with the postwar spread of democracies. In the late 1990s there were 179 democracies of 192 sovereign states, 93 percent of the world's governments. Sixty-nine nations had their first-ever elections in that decade. Three of the five newest democracies were former Soviet republics (BELARUS, ARMENIA, and KYRGYZSTAN), all of which had national elections in 1995. In Africa, TANZANIA and GUINEA joined the roster of new democratic countries the same year.

## Don River

THE DON RIVER IS one of RUSSIA's major commercial rivers, which, connected to the VOLGA through the 65-mi (105-km) Volga-Don Canal, allows river traffic to sail from Russia's interior ports as far inland as MOSCOW to ports on the BLACK SEA and beyond to the MEDITERRANEAN. The Don River basin also includes its most important tributary, the Donets, which flows through the northeastern corner of the UKRAINE, the most industrially active region of that country, known

for its coal and production of steel and heavy manufacturing machinery.

The Don rises near the city of Tula, about 125 mi (200 km) southeast of Moscow. It then flows for 1,220 mi (1,950 km), first southeast to a bend a few kilometers west of Volgograd (coming within 31 mi or 50 km of the Volga River), then southwest to its mouth on the Sea of Azov. It is at this bend where the rivers Don and Volga are joined by the Volga-Don Canal, built in 1952. The canal joins the Don in the Tsimlyanskoye Reservoir, one of Russia's numerous vast hydroelectric projects built in the Soviet era, with a large dam between the towns of Tsimlyansk and Volgograd.

The Don basin's largest cities are clustered below this point (Rostov, Bataysk, Novocherkassk) or along the industrial Donets basin in Ukraine (Kharkov, Lisichansk, Lugansk). Altogether, the Don basin drains 178,894 square mi (458,703 square km), most of it Russia's breadbasket (83 percent is cropland).

Known as the Tanais to ancient geographers, it was the center of Scythian culture in the centuries before and after the Christian era. It is the busiest trade river of south Russia, navigable for 800 mi (1,290 km), bringing Siberian raw materials and manufactured goods from the north to the warm-water ports of the south. Frozen during three months of the year, it is also occasionally hampered by severe spring flooding, but also large volumes of silt that make navigation in its lower reaches treacherous because of shifting sandbanks and shallows. Its entryway into the Sea of Azov, the Gulf of Taganrog, is one of the shallowest bodies of water in the world, with depths averaging a mere 3.3 ft (1 m).

## Drakensberg Mountains

THE DRAKENSBERG Mountains form one of the most scenic natural areas in SOUTH AFRICA. The mountain range straddles the eastern border of LESOTHO, a LANDLOCKED nation lying within the boundaries of South Africa, located about 150 mi (250 km) north-

*Sentinel Peak typifies the rugged terrain of the Drakensberg Mountains in South Africa and Lesotho.*

west of Durban. The name *Drakensberg* means “Dragon Mountains” in Afrikaans. The range is also known to the Zulu nation as “uKhahlamba” (the “Barrier of Spears”).

The Drakensberg Mountains are the southern extension of the interior highlands of Africa, rising to 10,826 ft (3,300 m) before dropping to the coastal lowlands near Durban. The Drakensbergs serve as the headwaters of South Africa's largest river, the Orange River, which flows west from the highlands of Lesotho to the South Africa-NAMIBIA border before emptying into the ATLANTIC OCEAN. The steep gradients and land use cause many of South Africa's rivers to have a high rate of runoff and soil EROSION.

Seasonality is reflected in dry, sunny winters (April to October) and summer rains (November to March). Rainfall varies from 15.7 in (40 cm) to 35.4 in (90 cm) of precipitation per year, with some areas occasionally receiving up to 78.7 in (200 cm) per year. A “rainfall line” denotes grazing and irrigated crops to the west and land more suitable for farming to the east. Record snowfalls (19.7 in or 50 cm) occurred in July 1994.

Bushmen (called “San”) have inhabited the basalt ESCARPMENT from thousands of years ago up until the late 1800s, leaving tens of thousands of rock paintings at over 500 sites. This is a major reason part of the mountain range was designated the uKhahlamba-Drakensberg World Heritage Site in 2000 by the United Nations.

The Drakensberg Mountains also hold numerous national parks, the most scenic of which is Royal Natal National Park, located at the northern end of the range. Here lies the Amphitheatre, a natural ring of thousand-meter high cliffs that includes multilevel Thukela Falls, the second-highest waterfall in the world.

In addition to cultural and scenic amenities, the Drakensberg Mountains also harbor high levels of biodiversity, much of this resulting from the steep elevation gradients. Ninety-eight of 2,153 plant species are endemic or near-endemic to the area; the almost 300 bird species include the globally endangered cape parrot and white-winged fluff-tail.

Despite efforts by Zulu kings to limit the range of trophy hunters, several wildlife species nearly became extinct from hunting here by the late 1800s. The eland, endemic gray rhebok, and clawless and spotted-neck otters are species populations exhibiting healthy recovery from this historic setback. Other traditional African wildlife that inhabit the Drakensberg Mountains include leopard, baboon, jackal, wildebeest, and zebra.

Historic battlefields dot the region, marking sites of the British-Zulu wars and British-Boer wars of the 1800s. Nearby towns and cities include Ladysmith, through which Mahatma Gandhi and Winston Churchill passed early in their careers. Ladysmith is the home of Ladysmith Black Mambazo, a musical group popularized globally by Paul Simon.

## dunes

DUNES ARE PILES of windblown sediment. Geomorphologists refer to dunes and other wind-created features as aeolian landforms. (Aeolus was the ancient

Greek god of the winds.) Geomorphologists also refer to dunes as sand dunes, as sand is the most common type of sediment in the deposits. Dunes sometimes include sand-size aggregates of clay, gypsum, or carbonate grains as well.

Dunes form when an obstacle (a low hill, rocky outcrop, cluster of bushes or grasses, etc.) slows down sediment-laden wind. Dune development requires a sediment source and a relatively strong wind. Sand dunes form in deserts and along low coastlines. In deserts, winds blowing across dry deflation-prone surfaces supply the sand. Coastal dunes depend on long-shore ocean currents to bring sand to beaches, and then steady winds blow the sand inland where the dunes form. In profile view, most dunes consist of three parts: a gently sloping (upwind) back slope, a sharp-edged or slightly rounded crest, and a steeply inclined (downwind) slip face.

Winds blow up the back slope side of the dune to the crest, crossing the crest at a 90 degree angle. Active dunes slowly migrate downwind as the winds push the sand-size particles up the back slope to the crest, where they slide down the slip face. Large dunes travel a few dozen feet or meters a year; smaller ones move up to 131 ft (40 m) a year. Active dunes quickly smother any vegetation that manages to take root on their surfaces.

Stabilized dunes are dunes anchored in place by deeply rooted vegetation. Dune stabilization occurs in semiarid and coastal areas where the climate is moist enough for grasses or small bushes to grow on the dunes. Precipitation and dew dampen the sandy surface to make it less mobile and less apt to smother developing vegetation growth. In some regions, climate change from a desert to a more humid climate or a reduction in sand supply accounts for dune stabilization. Anchorage may also be human-induced. Cultivating fast-growing grasses on dunes is one method; people plant the grasses to slow down dune migrations into agricultural fields and check sand from blowing into cities and towns. Artificial dune stabilization is usually only a temporary fix to an inexorable natural process of dune migration.

The most common dunes are barchan, transverse, seif, star, and parabolic dunes. The barchan is small dune that migrates across a surface that has little sand. It is crescent- or U-shaped, with narrow tips pointing down wind. Transverse dunes are only slightly crescent-shaped, and they occur where there is an abundant supply of sand. Transverse dunes often form fields of wavelike sand dunes whose slip faces consistently face the same direction. Seif dunes form in a generally

parallel arrangement. *Seif* is the Arabic word meaning “sword,” an apt expression for this long narrow dune. Seif dunes can be tens of kilometers in length and several tens of meters high. Seifs have multifaceted slip faces, as variable wind directions affect them. The changeable winds cause the dunes to migrate in the direction of their longitudinal axes.

For this reason, geomorphologists refer to seifs as longitudinal dunes. Variable winds cause star dunes to have even more complex slip faces than longitudinal dunes: star dunes have central peaks from which several crests (arms) radiate. Coastal dunes are usually of the parabolic type as sea breezes imprint a subtle parabola (bowl) shape on the dunes’ back slopes. This

depression gives the parabolic dune a U-shape plan in which the arms point upwind. Winds from powerful storms that form over the ocean sometimes accentuate parabolic depressions by creating blowouts—dunes with very deep excavations in their back slopes.

## earthquakes

**STRONG GROUND** motion occurs whenever energy, conserved as strain in the Earth's crust or upper mantle, is released instantaneously. In such an event, commonly called an earthquake, energy radiates from the source of release in a series of waves. As waves propagate through rock and other elastic media, they cause periodic displacements (movements up and down or back and forth) that are experienced as shaking. While the vast majority of earthquakes, or seismic events, release too little energy or occur at too great a distance to cause this experience, a small percentage are perceived as shaking. A smaller number still can cause damage, death, and devastation. Energy transferred through the impact of extraterrestrial bodies, such as meteorites, and from detonations of explosive materials can also cause strong ground motion. In most cases, the energy so released is too slight to effect more than a small area.

### NATURALLY OCCURRING EARTHQUAKES

The crust of the Earth is in constant motion as new rock, formed when magma rises to the surface of the crust, displaces older crustal rock. To complete a cycle, older rock returns to the Earth's mantle, replenishing sources of magma. One can imagine a perfect geometry for the Earth's surface that might accommodate this

process without strain—it would resemble the mechanics of an escalator. But the real surface of the Earth, which is spheroidal, is far less than ideal. The creation of new rock requires constant readjustment of the spheroidal surface. Taken together, these processes of creating of new rock, the destruction of older rock, and the readjustment of rock on the spheroidal surface are called **PLATE TECTONICS**.

Crust at the Earth's surface is not continuous. The crust is composed of a set of plates, each moving relative to adjacent plates. This movement causes strain wherever movement is impeded or opposed. The resulting strain is expressed in crustal rock as deformation. Deformation is expressed in crustal rocks through several characteristic structures. Folds in the crust are one such structure. Faults—surfaces within the crust that accommodate contrary motions of rock on either side of the surface—are another. While movement along some faults can be nearly continuous, the geometries of other faults can result in discontinuous movement and will store strain. Over time, strain in the rock will increase to a point where the competence of the rock is insufficient to store additional strain. At that point, the fault surface will rupture. The subsequent release of strain in such a rupture is the proximate cause of earthquakes.

The geometries of fault surfaces are numerous and complex. Structural geologists recognize three basic

*An earthquake that struck on July 11, 1927, in Palestine reduced this house in Nablus to a mere ruin.*

fault types. These are the normal fault, the thrust fault, and the strike-slip fault. Normal faults occur where tectonic movement, resulting in vertical displacements of crust, stretches the crust. Thrust faults also displace crust vertically, but along a lower fault angle and as a result of compression rather than tension. In strike-slip faulting, displacements are horizontal. The San Andreas Fault, running from under the Salton Sea to a point north of San Francisco, is a well-known example of a strike-slip fault. All three of these geometries are generalizations; many faults result in both horizontal and vertical displacement. Moreover, earthquakes generally occur within a fault zone, rather than occurring repeatedly along a single fault plane.

When strain is released in the rupture of a fault surface, energy dissipates as mechanical motion expressed as oscillations, or waves. Seismologists, scientists who observe and study ground motion, have found that the waves generated by fault ruptures take several forms, each with distinct properties. Surface waves generate

both vertical and horizontal oscillations at the Earth's surface. Primary (P) and secondary (S) body waves propagate through crust at different velocities. Primary waves propagate through all layers of the earth, but secondary waves do not propagate through fluids and therefore do not pass through the Earth's core. The different properties of waves provide seismologists with a variety of techniques for pinpointing the sources of waves (at a focal point on the fault plane, or focus, and at a point on the surface above, known as the epicenter), the characteristics of fault displacement, and a means for studying the Earth's core and mantle.

Because the crustal rock and sediments at the surface of the Earth are not uniform, wave propagation through the crust is not uniform. Surface waves, which cause most of the damage in earthquakes, exhibit different properties when propagated through different thickness and densities of rock; wave motion can be magnified when surface waves pass through unconsolidated sediments, especially sediments with high ground water content. Often, such sediments experience liquefaction, in which the competence of the sediments is severely diminished. The greatest damage in earthquakes usually occurs in structures built on such sediments, as in the Marina District in San Francisco, which was severely damaged in the Loma Prieta earthquake of 1989.

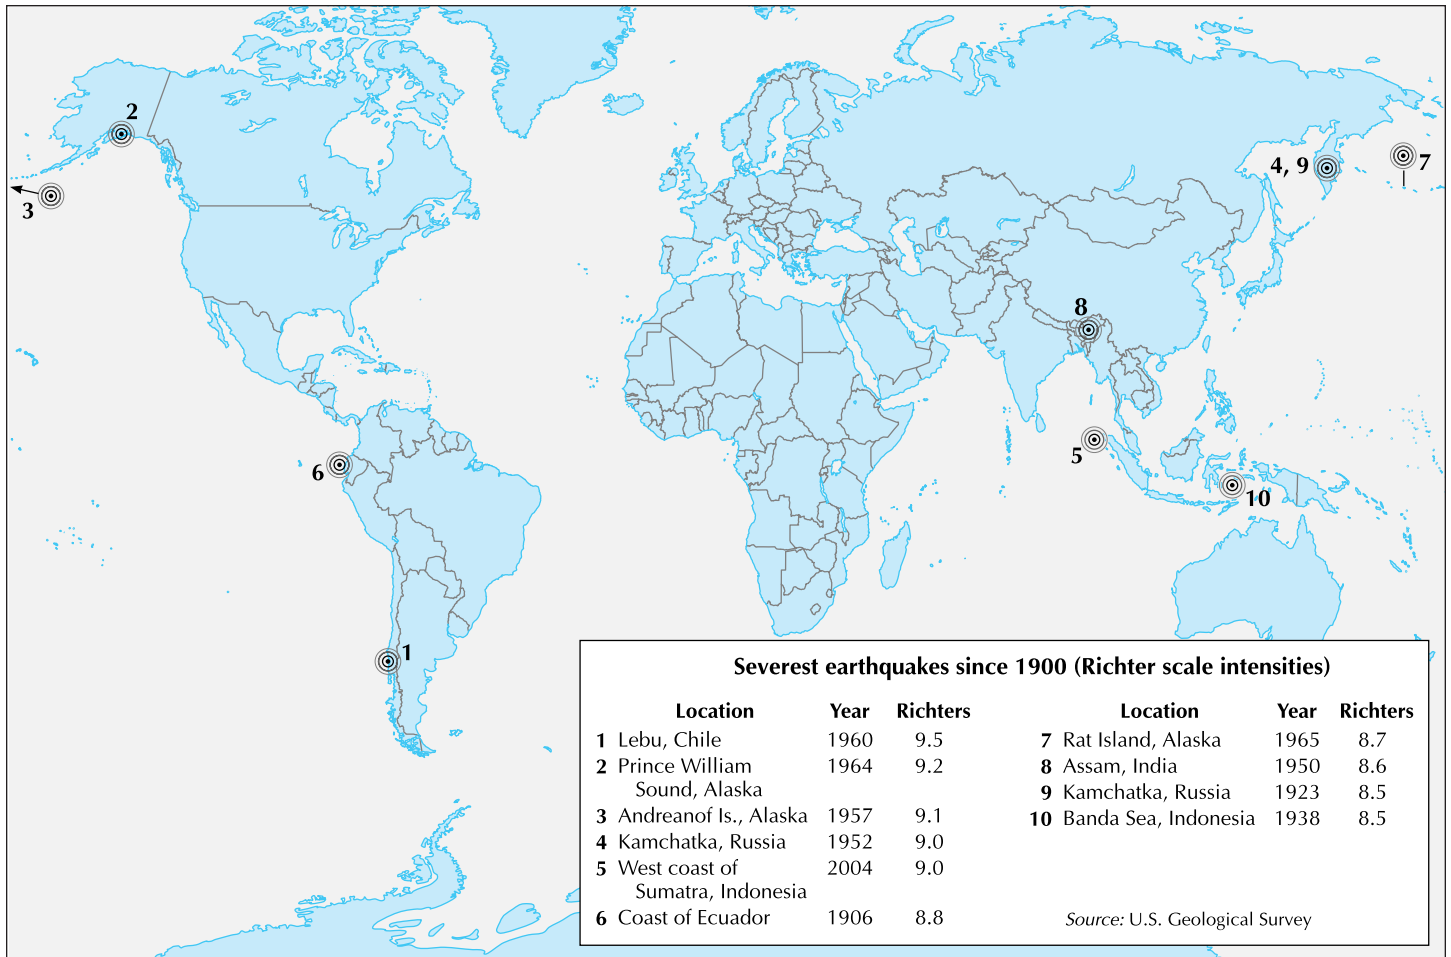

### EFFECTS OF EARTHQUAKES

For most organisms, the effects of earthquakes are minimal compared to the effects of other natural catastrophes such as volcanic eruptions, floods, and large storms. Tall trees growing near a fault may be "topped" by side-to-side motion in an earthquake of sufficient intensity, and domesticated animals have been observed to alter their behavior as a precursor to an earthquake. Liquefaction of soils may cause extensive damage to forests. Nevertheless, the effects to most organisms are benign.

The same cannot be said for most modern human populations in cases of earthquakes of moderate to high magnitude. The Modified Mercalli Scale of earthquake intensity, also known in revised form as the European Macroseismic Scale, attests to the effects that very strong ground motion can have for built environments and the assortment of objects that we create and use.

An earthquake at level V in the 12-level scale, for instance, is "felt by nearly everyone; many awakened. Some dishes, windows broken. Unstable objects overturned. Pendulum clocks may stop." At level XII, dam-

In the United States, over approximately the past 100 years, large earthquakes have caused extensive damage in San Francisco (1906 and 1989); Anchorage, Alaska (1964); and in the Los Angeles area (1933, 1971, and 1994).

age is “total. Lines of sight and level are distorted. Objects thrown into the air.”

Historically, earthquakes have posed severe challenges for human inhabitations, involving loss of life, destruction of inhabitations and property, and—in some cases—political upheaval. Earthquakes have been recorded throughout human history, and there are records of earthquakes for most great civilizations. The Minoan Civilization on Crete, for example, is believed by many historians to have faltered or collapsed due to earthquakes and tsunamis during the second millennium, B.C.E.

In November 1755, a large earthquake devastated the city of Lisbon, in Portugal, killing 40,000 individuals and destroying most structures. The earthquake was felt throughout the Iberian Peninsula and elsewhere in Europe, and was recorded in a number of contemporary accounts. A fictionalized account of the

earthquake serves as a climactic event in François Marie Arouet Voltaire’s literary work, *Candide*.

Within the contiguous United States, the largest event in recorded history was a cluster of three large earthquakes in 1811 and 1812 centered near New Madrid, MISSOURI. The largest of these, estimated at greater than 8.0 on the Richter scale, occurred in December 1811. The earthquake cluster caused changes in the course of the MISSISSIPPI RIVER and devastated large areas of forest.

Over approximately the past 100 years, large earthquakes have caused extensive damage in San Francisco (1906 and 1989); Anchorage, ALASKA (1964); and in the LOS ANGELES area (1933, 1971, and 1994).

In religious cultures, the causes of earthquakes were generally ascribed to acts of the gods, or of God. The roots of western philosophy, however, looked to secular causes; Aristotle explained earthquakes as

winds trapped and released from subterranean caves. The Chinese developed a rudimentary (but elegant) seismograph. With the scientific revolution and the subsequent Enlightenment, the search for causes of earthquakes increased. But it was the San Francisco earthquake of 1906 that spurred greater concentrations of scientific interest in earthquakes, resulting in the “elastic rebound” theory, devised by H.F. Reid in a report on that earthquake.

In the 1920s, the newly founded California Institute of Technology and its Seismology Laboratory, with a network of seismographs created to monitor and study earthquakes along California’s San Andreas Fault and ancillary faults, became a magnet for seismologists. There, Charles Richter and Beno Gutenberg devised what has become known as the Richter scale, a logarithmic scale of wave motion amplitudes that yields a measure of the magnitude of an earthquake. Also working in the Seismo Lab, Hugo Benioff developed an interest in studying deep focus earthquakes. Results of his studies were important for the later development of plate tectonics; Benioff’s observed patterns of deep-focus earthquakes were later explained in plate tectonics as part of the subduction process.

In the aftermath of the 1964 Anchorage earthquake, policy makers became interested in seismologists’ hopes that earthquakes might be predictable. This interest may have been related to Cold War politics; a science and technology for predicting earthquakes could lead to evacuations and might save many lives, demonstrating the capacity in the United States for surviving a nuclear attack of comparable destructive force. By the 1980s, primary interest in policy shifted from prediction to preparation and mitigation: engineering better buildings and infrastructure, and strengthening building codes.

Interest in earthquake prediction has not abated. In the 1980s, the U.S. Geological Survey created an extensive system of monitoring devices in Parkfield, California, a site of generally dependable movements along the San Andreas Fault. Data collected in the September 28, 2004, earthquake in this location is presently being analyzed for evidence of precursor activities that may someday permit reliable predictions.

UNIVERSITY OF CALIFORNIA, SAN DIEGO

## East Timor

**Map Page** 1124 **Area** 5,853 square mi (15,007 square km) **Population** 997,853 **Capital** Dili **Highest Point** 9,778 ft (2,963 m) **Lowest Point** 0 m **GDP per capita** \$500 **Primary Natural Resources** gold, petroleum, natural gas, manganese, marble.

THE ISLAND OF Timor, in the Indonesian archipelago, is no stranger to struggle. Disputed between the Dutch and Portuguese since the late 1500s, the island was officially split when the eastern portion declared independence from PORTUGAL in 1975, only to be immediately claimed by INDONESIA, setting off 25 years of violence and destruction.

The Democratic Republic of East Timor (or Timor Leste) forms the eastern half of the island of Timor, the easternmost (and largest) of the Lesser Sunda islands (in fact, “timor” simply means “east” in Malayan languages). The new nation also includes an enclave in the western half of the island (Oecussi-Ambeno), and an island off the northern coast, Ataúro. Timor is located about 620 mi (1,000 km) east of JAVA, and about 300 mi (450 km) northwest of AUSTRALIA. The island is volcanic in origin and its terrain is mostly mountainous, with difficult access due to steep coasts and coral reefs.

Timor thus remained little explored until the later 20th century, and European influence was restricted to a few coastal settlements (mostly on the north coast) dependent on plantations of coffee, rice, sugar, and coconuts. The interior mountains contain considerable minerals, including gold, manganese, and marble, but these are largely unexplored. The discovery of large re-

serves of offshore petroleum and natural gas promises much for the future of the country, but is also a continuing source of tension between rival claims of the Indonesian and Australian governments.

Both Portuguese and Dutch trading posts were established on Timor in the 16th century, but it was not until 1913 that the Dutch formally recognized the Portuguese position in the eastern half of the island. Long after the Dutch East Indies became independent as Indonesia in 1949, the Portuguese colony of Timor declared itself independent in 1975. It was immediately occupied by Indonesia, however, and forced to assimilate with the rest of the island. After 20 years of violence resulting in the loss of between 100,000 and 300,000 lives (killed or missing), a United Nations-supervised referendum in 1999 resulted in renewed independence in May 2002, and East Timor became a new nation in September 2002.

The country's capital, Díli, built by the Portuguese in the 1620s, is located on the northern coast of the island and is being rebuilt after near complete destruction in 1999. At independence, East Timor was one of the world's poorest nations, with 70 percent illiteracy, 12 percent infant mortality, and an average life expectancy below 50 years. The country relies mostly on exports of timber and coffee, while it waits for resolution of its struggles with Australia over exploitation rights of the Timor Gap, the region of seabed off the southeast coast with large fossil fuel reserves. A settlement between Australia and Indonesia was reached over this prize in 1989, when East Timor was still under Indonesian occupation, and Australia is now unwilling to give up concessions to an area potentially yielding \$29 billion in revenues. This conflict remained unresolved in 2004.

## Easter Island

**POLITICALLY,** EASTER ISLAND has belonged to CHILE since 1888, though it lies some 2,200 mi (3,500

*Anthropologist Thor Heyerdahl proposed Easter Islanders originated in Peru, built a balsa raft, and sailed it to prove the point.*

km) west of the coast of Chile and just south of the TROPIC OF CAPRICORN in the PACIFIC OCEAN. Its nearest neighbor is PITCAIRN ISLAND 1,132 mi (1,819 km) to the west. The major settlement is Hanga Roa. Easter Island enjoys a subtropical climate tempered by oceanic influences; the annual temperature ranges from 86 degrees F (30 degrees C) in January/February to 57 degrees F (14 degrees C) in July and the annual precipitation is 45.2 in (114 cm).

The island has an area of 64 square mi (166 square km) that is triangular in shape and composed of volcanic rocks. There are three extinct volcanic peaks, the highest is Maunga Terevaka at 2,086 ft (652 m) and between which there are gently rolling lava hills. Two of the volcanic peaks have lakes in their craters that are sources of fresh water. Geologically, the island is young, having been formed by volcanic eruption on the Nazca Plate, a crustal "hot spot," in the last 2 to 5 million years. The rocks are andesites and basalts, which have produced alkaline to neutral soils rich in clays and loams. The consolidated volcanic ash, or tuff, in

*The Moai statues have puzzled ethnographers, archaeologists, and visitors since the first European explorers arrived in 1722.*

the volcanic crater of Rano Raraku provided the material for the monoliths, or statues of large heads known as Moai, which are located along the coast and for which the island is famous.

### DEFORESTATION

The current vegetation is grass savanna and is devoid of natural forest/woodland, though there is convincing evidence that several species of trees and woody shrubs were once present, including at least one tree palm. Deforestation had occurred by the time Europeans arrived and its completeness is considered to represent an ecological disaster; certainly soil EROSION is a problem in places.

The island was first seen by the Dutch explorer Jakob Roggeveen, on Easter Sunday, April 6, 1722, an occasion that gave the island its name. There have never been any native mammals but there are indigenous insects, one species of lizard and several land birds, though at least six of the latter have become extinct from human impact. Some afforestation in the in-

terior of the island has been undertaken featuring eucalyptus species, and rodents such as rats and mice have become naturalized.

The origin of the Easter Islanders has been controversial. The anthropologist Thor Heyerdahl, proposed that they originated in PERU and built a balsa raft. He imitated their journey with native boats and sailed from Peru to the island to prove that the trip was possible. However, it is now accepted that they originated in Polynesia, possibly from the Marquesas Islands, and arrived on Easter Island about 600 years ago. The Moais, huge native statues, of which there are more than 1,000, were erected between 1000 and 1650 C.E. They are a major tourist attraction and there are rock paintings (petroglyphs) which also depict human life. The Rapa Nui National Park, covering most of the island, was established in 1935 to protect the archaeological remains. The islanders used Rongorongo script, the sole written language of Oceania.

Today, the population is about 3,000, having recovered from a major decline following initial contact with Europeans which brought disease and slavery. Tourism is a major source of work and income. There is a rich artistic tradition involving carvings, tattooing, and music.

## ecological niches

IN CONTEMPORARY ecology, the term *ecological niches* is referred to as the position occupied by representatives of any life form (usually alive) in biocenosis, and, at the same time, the smallest unit of a habitat that is occupied by an organism. The notion reflects an organism's or species's place in the community, taking into account not only its tolerance to natural (physical) agents, but its interaction with other organisms as well. The ecological niche concept originated as an attempt to describe the general role of species in the community

and to differentiate on a theoretical level population, community, and ecological systems. The term had been introduced in 1917 by J. Grinnell, who interpreted it in a spatial sense as the ultimate distributional unit of a species. Later C. Elton (1927) concentrated mainly on niche functional aspects when describing an organism's place in its biotic environment in connection with its nutrition and animals.

The middle of 20th century marked a multidimensional approach to the niche concept in the works of L. Ramensky (1924), E. Odum (1968), and others. The multidimensional approach to niche comprehension allows scientists to conceive how species are connected with each other and, in such a way, enhances the understanding of a community's internal organization.

Further development of the niche concept is connected with the name of G. Hutchinson. In 1957, he interpreted niche as hyperspace, in frameworks of which conditions of the ambient allow unrestrictedly durable existence of specimen or species. According to Hutchinson, niche is defined by a general set of environment variables, to which species must be adapted (physically, chemically, biotically) and in which a species population lives and replaces itself indefinitely.

Such niches could be described mathematically with the help of quantitative characteristics of every environment's variable spatial coordinates. Hutchinson distinguished fundamental (now often called potential) niche (the whole set of optimal conditions that could be occupied by a species in its enemies' absence) and realized niche (a real set of conditions in which a species usually exists).

Today, a niche is often regarded as a way by which a species population fits into a certain community and in such a context concentrates on a species's connections in one community. So the niche concept also is concerned with the functional role of an organism in community (for example, its trophic status) and its position in relation to external factors of its habitat (such as temperature, humidity, etc.). It is especially useful for understanding the current distribution of sources among all niche inhabitants.

The latest developments in the framework of ecological niches are connected with a discussion about their attribution as a basic property of community or species. Some researchers believe that any niche is generated by its inhabitants, and its features are defined by the role that its creator is playing in its environment. Others regard niche as a community attribute and deny its significance in any other context. They reveal the phenomenon of ecological equivalence (or the principle

of convergent evolution): A niche is created by biotic and abiotic ecosystem components and exists a priori. It becomes filled in the course of a species's adaptations taking place during evolutionary changes; such species' adaptations should be similar even if these species are not interrelated.

### NICHE CHARACTERISTICS

Theoretical and empirical development of the ecological niche concept has put forward a series of niche characteristics, a major part of which is defined by function of utilization (or species activity distribution) along the resources' gradient. Most important among niche characteristics are the principle of competitive exclusion, niche width, niche axes, niche dynamics, niche interlocation, and so on.

The principle of competitive exclusion (or Gause principle) was proposed in the 1920s as the result of experimental investigations by G. Gause and J. Grinnell. Accordingly, two ecologically identical species could not survive simultaneously at the same place, or a niche is occupied by only one species. It was mathematically confirmed by the equation of Lotka-Volterra and has become one of the basic principles of ecology. In connection with the niche concept, attention should be paid to its corollary: If two species co-exist, they should differ ecologically, so every species has its own niche.

Niche width (or its size) notion is inherent to a multidimensional approach to niche interpretation. In its framework, it is defined as a general amount of all diversity of different features used by the population. Most often, it is identified through species activity distribution (resources utilization spectrum). Niche axes is a relatively new notion with a minimally independent set of limits in relation to species factors. It describes a series of important variables, such as form of population response to the axis challenge, relative width of species distribution along certain axes, grade of species overlapping, species's relative position along the axis, and other factors.

The niche dynamics concept envisions investigation of niche changes in at least three contexts. In an evolutionary framework, short-term, life cycle, and generational changes could be distinguished. The width of a realized niche also changes in response to competition and in relation with resource level. Community space changes in accordance with daily or seasonal rhythms. The niche interlocation concept describes niche differences, first of all, with time and place of activity and with ways of other species' communication. In such a

context, scientists have distinguished occasional (non-overlapping), discrete, and overlapping niches.

## ecology

ECOLOGY IS THE study of the interaction between an organism and its physical environment. Human ecology specifically focuses on humans as a group of organisms and their mutual relationships within the habitat. The term *ecology* has its origin in two ancient Greek words: *oikos* (house or habitat) and *logia* (words or teaching). Thus, the concept of ecology has its origin the Greek *oikologia*, and could be rendered "teaching about the habitat." This article explores three dimensions of ecology in order: human ecology, political ecology, and biological ecology. The central theme that unites these three subsets is how humans interact with the Earth.

### HUMAN ECOLOGY

Often, the term *human ecology* is used interchangeably with *cultural ecology*. The human geographers find dialectical relationships between people and nature and consider cultures as a meeting ground of the two major elements of ecology: humans and environments. Each culture grows in a specific natural environment along with each human group and its living on the Earth.

Thus, it is crucial for human geographers and cultural geographers to study interactions between humans and environment to understand spatial variations of culture, its development, and distributions. Human ecology consists of these two approaches: 1) how an environment impacts and shapes a culture; and 2) the human influence on the habitat and making of cultural landscape through culture building. Employing these approaches, human ecology encompasses several branches and concepts, and this article discusses a few of them to facilitate understanding of the dialectical human-environment relationships.

Cultural ecology studies the mutual influences between human groups and the environment. Cultural ecology often qualifies culture as an effective mediator or medium for humans to facilitate their adaptation to physical environments. This process is called an adaptive system, and cultural ecologists render this system cultural adaptation. In this venue, cultural ecologists recognize the importance of studying plant and animal adaptations to understand human-environment relationships. Cultures are the basis of successful human adaptation to environment and its change through time.

Historically, food, clothing, shelter, and knowledge served to reduce human difficulties to subsist in the midst of powerful nature. These cultural traits are examples of an adaptive strategy, and the strategy includes almost all aspects of our culture that enables us to prosper on the Earth. Although cultures function as a meeting ground between human and environment, we should note that the same or similar physical environment produces no identical cultures. This fact indicates that each group of people employs the unique strategy to survive in its natural setting. The interaction between the unique cultural traits and surrounding environmental conditions always result in a making of individual adaptive processes. Thus, we can observe an omnipresent two-way relationship between human and environment.

The approach and themes within cultural ecology often function as the crossroads of cultural and physical geographers, and it is closely identified with four schools of thought: environmental determinism, possibilism, environmental perception, and humans as modifiers of the Earth.

All of the four pillars are particularly revealed in the studies in ethnic geography, folk geography, and the examination of ecology in popular cultures is another vital perspective in geography as an academic discipline today.

Generally, folk groups are more involved with their physical environments, thus tend to establish an intimate relationship with nature. Therefore, cultural ecology as a geographical discipline maintains a relatively close association with folk geography. Folk adaptive strategies are based on sustainability and are usually the opposite from those of popular culture. Sustainability is judged by how people use natural products and consume energy in a way that does not destroy the environment.

Among folk groups in particular, human interaction with habitat is intense as the people gain their

livelihood directly through the Earth: farming, mining, extracting other resources, herding, hunting, gathering, and fishing to name but a few. The folk ecology and adaptive strategies are usually inseparable, and this interrelationship is revealed in the making of folk languages. For example, folk languages tend to have the vocabularies based on their historical exploitation of the habitat as well as their religious act to protect themselves from environmental hazards.

The folk languages are often employed to tell stories; folktales were passed on in honor of their heroic figures, proverbs were charged with wisdom about the weather and the farming, and their traditional architecture show us how the folk groups successfully balance available resources and climate. How the folk groups subsisted is called the folkways, and these processes historically facilitated successful human adjustment to the physical environment.

Folk ecology can be similar to religious ecology by seeking the relationship between religion and nature; religious ecology studies how folk religions help guide people's local modification of the environment and shape their perception of nature. The dialectical relationship between humans and nature is again witnessed in this context—the habitat influences the formation of religion, and human desire to control the land increases as the religious hierarchy is facilitated in the community.

It is obvious that folk cultures maintain close contact with the Earth and are more sensitive about the qualities of habitat than popular cultures; this is because folk survival and prosperity tend to be more at the stake of physical surroundings. However, folk people, too, shape the landscape through their culture building, and it is not necessarily true that folk groups live in perfect harmony with their environment. It is always very difficult to maintain good balance between the two organisms: human and environment.

### ETHNIC ECOLOGY

Ethnic ecology studies how certain ethnic groups interact with their habitat through the process of making cultural landscapes. Ethnicity has a close link to cultural ecology as much as folk cultures do, and a strong correlation exists between people and physical environment in ethnic culture regions, in ethnic migration, and in survival of ethnic groups. Ethnic groups are occasionally created in a remote place from their source region. This is often caused by migration and/or relocation diffusion. Since those groups settled in distance, cultural preadaptation must be considered as an eco-

logical element. Preadaptation is a process based on a collection of adaptive traits, such as behaviors, ideas, and practices, possessed by a group prior to migration. This ability gives them the chance to survive in the new environment after migration or relocation diffusion. Preadaptation mostly occurs in groups migrating to an environmentally similar place to their original home, and the adaptive strategy from their source region should work effectively in the new destination.

Environmental perception of the new land is another key to understanding ethnic ecology. There is a general tendency for immigrants to unconsciously associate their new home with their abandoned homeland, thus finding the new home more similar to their original home than reality. In other words, they emphasize the similarities and minimize the differences between old and new homes, and this perception often causes some extent of distortion.

This perceptual process occasionally caused problems for ethnic farming groups, particularly early Western European immigrants to Americas. Sometimes crops that thrived well in the old homeland were not adaptive to the particular American environmental setting. This collapse in agriculture and farming resulted in economic breakdown, and it is often the case that the ethnic settlement was deserted. This result can be referred as an example of cultural maladaptation.

### ECOLOGY OF POPULAR CULTURE

In contrast to folk culture, ecology of popular culture is less evident because its link to the physical environment is weaker than that of folk culture. The major difference lies in its involvement with industrialization and technology. Thus, popular culture is often said to propose a mechanistic view of nature. The advent of modernity demolished direct human confrontation and involvement with many environmental forces, and people in popular cultures can cause ecological disasters as much as becoming their victims. In popular culture, knowledge of the physical environment is mainly gained indirectly through books, mass media, and safe and harmless artificial environment, thus there are little direct involvement with the Earth. This indirect relationship with habitat is likely to distort human environmental perceptions. Furthermore, the existence of popular culture leaves a dominant impact on ecosystems.

One model of distinctive interaction between popular culture and ecology is observed in how and where the members of popular culture wish to spend their leisure time. People in popular culture now spend

much free time in areas outside the cities, or at least this is what they wish. The last quarter of the 20th century witnessed the rapid growth of the demand for recreation zones, often consisting of artificial wilderness. Such an influx of people in former “wilderness” results in damage to the physical environment, which includes our habitat itself. It is ironic that the population cluster in cities and suburbs causes greater impact on the rest of the world; people who grow up in popular culture tend to carry their cultural values into nature.

The boom of recreational tourism is now an international phenomenon, and some countries have made natural areas more accessible to people, which results in harming the habitat. The UNITED STATES is one of the countries that separates national parks from wilderness areas. Yet the human impact on the environment remains a severe problem to this day. In this context, the cultural ecology of the city seeks how we should understand the inseparable relationships between the urban settings and their interplay with the physical environment through human involvement. The theme of cultural ecology helps us to organize information about this city-nature interaction within the framework of human-environment relationship.

### ECOLOGY IN POPULATION GEOGRAPHY

The theme of human ecology is applicable to the study of population geography as well. In a given ecosystem, a successful adaptive strategy allows a people's survival and the reproduction of population at the most basic level. However, population is always at the sake of the availability of local resources regardless of adaptive strategy, and climatic factors influence the people's choice of settlement locations.

Another prominent factor that affects population distribution is disease. Some diseases may attack domestic animals and deprive the people of food. Thus, such diseases may affect human population density in a given location. Perception of the physical environment also plays a major role when a group of people chooses where to settle and subsist—people are almost always in search of similar environments to their original home.

Various cultural groups often see the same physical environment in different and unique ways, and these individualized responses to a single environment also influence human distribution patterns. Adaptive strategies include how people modify their habitats through the development of their cultures. Particularly, significant alterations of physical environment often occur in

densely populated areas. Adaptive strategies are not always sustainable, and at present densities, these population densities are a particular reason why we face a worldwide ecological crisis in terms of supplying food and resources appropriately. Thus, the population explosion and the ecological crisis maintain a two-way relationship.

### POLITICAL ECOLOGY

This approach focuses on political phenomena on the Earth that revolves around the interrelationship between humans and the environment. Thus, political activities in a natural habitat bear a prominent focus, and therefore have a strong link with political geography. Political ecology studies how political and cultural processes shape society (human)-nature (environment) relationships. In many cases, people have a strong attachment to their habitat through the building of cultures. Political ecology can be considered as a marriage of geography and anthropology and is characterized as an interdisciplinary approach rather than a unified methodology associated with one specific discipline.

Environmental changes affected by political phenomena in indigenous or ethnic societies are typically common subjects in political ecology, but recently, the approach is increasingly applied toward industrialized societies to analyze diversities of human relationship and conceptualization of nature based on geopolitics and several other prominent theories.

Although geopolitics is often singularly associated with political geography, the idea of geopolitics is inseparable from the importance of terrain, soils, climate, natural resources, and other elements of the physical environment to our political society. The term geopolitics is often used to describe the influence of habitat on political entities. On the other hand, political authorities have powerful potentials to modify environment through the scheme-organized alteration of the landscape and even in the name of environmental protection. In these ways, political entities influence and are influenced by the physical surroundings, and here again, we come across with a two-way relationship between human and environment.

In the past, a country's survival was enhanced by “folk fortress,” which is a natural stronghold, such as surrounding mountain ranges, deserts, or seas; bordering marshes or dense forests; or outward-facing ESCARPMENTS. The folk fortress was a valuable natural protection of the city and people by shielding an entire country or at least its core area. Without natural defense, for example, Korea, a land bridge leading from

CHINA to JAPAN, has repeatedly been threatened by both neighbors. Korea's history tells us how difficult it is for a country without natural protection to maintain its independence and sovereignty. Distribution of terrain is closely related to the concept of the folk fortress. We agree that an ideal country has mountains and hills around its edges and plains in the interior to provide sufficient fortification and comfortable space for people's settlement to facilitate defense and to heighten identity of a cohesive country. FRANCE comes very close to the ideal in terms of its physical setting, but very few countries in the world enjoy similar environmental boundaries.

Other desirable borders are mountain ridges because they stand out on the landscape and cross thinly populated countrysides. In contrast, not all the topographical features are helpful in making of efficient borders and a cohesive country. Rivers usually do not serve as ideal borders because their nature of changing course and flowing through densely settled valleys, create potential problems for the countries on either bank. An undesirable arrangement of physical features are called environmental barriers and may disrupt a country's internal unity and isolate one part of a country from another. Environmental barriers grow separatist sentiments easily, such as internal mountain ranges in the case of PERU and SPAIN that provide guerrillas with potential bases. Both Peru and Spain have problems of internal unity, and it can be said that this is partly because of their unfavorable physical settings.

In comparison, seacoasts serve as the most efficient borders for making independent countries, as is represented by AUSTRALIA. The Australian seacoasts provide excellent natural boundaries against expansive or acquisitive neighbors. However, we should not forget that there are always exceptions to these generalizations, such as HAWAII, CUBA, and the PHILIPPINES. These interactions between human territoriality and topographical arrangements recur in several theories in political ecology as well as political geography.

Increasingly today across the world, the term *political ecology* has a far more restricted meaning than the scope discussed above. It refers to a form of political activism dealing with the issue of disputes of who controls natural resources and who makes the political decisions that impact the habitat and indigenous population. Power games and the politically charged environmental consequences of the struggle between haves and have-nots become the center of the new political ecology. Many political actions and decisions have a significant impact upon habitat, and warfare is

the most devastating of all political phenomena. War destroys resources systematically, and it is unfortunate that warfare has been a favored practice to resolve political conflicts throughout history.

From an ecological perspective, environmental catastrophe goes on as a result of modern high-tech warfare, which destroys the delicate balance between human and habitat. Even military exercises and various tests affect habitat severely, as is the case with a drastic oil spill. The first world's desire to control resources and territories often resulted in destruction of habitats and the displacement of indigenous peoples by the people of political economic power.

The lumber industry, commercial fishing, the development of open lands, and other enterprises are often seen as ecologically destructive, although these are not always directly involved with politics. It is time for us to rethink human involvement with habitat from an ecological point of view, and political ecology gives us fundamental insights to deal with this world. The United States is one of the countries that has a Green Party to pursue a political-ecological agenda, and the existence of this political party represents increasing concern of human impact.

## BIOLOGICAL ECOLOGY

This approach is based on the idea of ecosystem, which includes all the plants and living creatures in a given area in relation to their physical environment. The term *ecosystem* is a contraction of the phrase *ecological system*, which encompasses biological ecology. Biological ecology has a closer affiliation with the domain of PHYSICAL GEOGRAPHY, yet due to the nature of ecology as a mediator of all types of geographers, biological interpretation of the Earth also contributes to the studies of cultural geography.

In studying the Earth from biological ecology perspectives, the concept of biota serves as one of the foundations of this approach. The term *biota* refers to the total group of plant and animal life in a region. Biota is subdivided from flora to fauna. An ecosystem includes biota, that is, all the organisms, in a given area, but it is more than a community of plants and animals. The ecosystem as a concept is based on the holistic interactions among and between organisms. The ecosystem also involves the nonliving portion of the environment, which includes nutrients and energy, such as soil, rocks, water, sunlight, and atmosphere.

Thus, an ecosystem is an essential collection of plants and animals along within the surrounding environment and all the interactions among these organ-

isms. The energy flow among the various components of the ecosystem plays a crucial role in biological ecology, as it is responsible for determining how a biological community is built.

Another fundamental concept of biological ecology is called a BIOME. A biome provides us with the most appropriate scale for understanding world distribution patterns of species and identifies recognizable assemblage of plants and animals through interaction with its environment. A biome is usually classified on the basis of its dominant vegetation along with the bulk of the biomass, which is the total weight of all organisms in the biome, as well as the most obvious and conspicuous visible component of the landscape, such as tropical RAINFOREST, DESERT, and TUNDRA.

The survival of plants and animals depends on an intimate and sometimes precarious set of relationships with other elements of the environment. Throughout environmental relationships, there are two major factors at work: intraspecific competition, which happens among members of the same species, and interspecific competition, which exists among members of different species. Both plants and animals compete with one another in search of light, water, nutrients, and favorable habitat in a dynamic environment. There are recognizable and predictable patterns of biotic distributions based on environmental relationships.

Various climatic factors play a dominant role as the most prominent environmental constraints on biological ecology at almost any scale. The four major components of CLIMATE are light, moisture, temperature, and wind. Light and photosynthesis are responsible for activating plants to produce stored chemical energy, and light also has a significant influence on determining the shapes and sizes of plants.

Moisture is the second climatic factor to characterize biological ecology. The broad distribution patterns of the biota are mostly determined by the level of moisture. The process of biotic evolution has been characterized by the adaptation of plants and animals to scarcity, abundance, or excess in moisture availability. In biological ecology, moisture is often synonymous with water.

Although the availability of water is largely determined by these atmospheric conditions, it is not always dependent on climate alone, as the relationship with precipitation evaporation should also be observed. Air and soil temperature are also important to biotic distribution patterns. Moderate temperatures attract more species of both plants and animals that cannot survive in cold regions. Wind assists in creating ecosystems by

influencing biotic distributions with its physical strength of causing biota frying and sometimes even violently uprooting trees. On the positive side, wind sometimes aids the dispersal of biota by carrying pollen, seeds, lightweight organisms, and flying creatures to contribute to biological diversity in an area.

Characteristics of soil that vary from one region to another and its relationship with local organisms are known as edaphic factors. Edaphic factors bring major influence to biotic distributions. These factors have a direct and immediate impact on flora, but the impact is usually indirect on fauna thanks to most animals' mobility. As long as we live on the Earth, soil is a major component of the habitat of any vegetation, and its characteristics significantly determine rooting capabilities and nutrient supply through soil texture and structure, human existence, chemical composition, and relative abundance of soil organisms.

In global biological ecology, general topographic characteristics are the most important factors affecting distribution of flora and fauna, including human settlements. For example, the existing species of plants and animals in a desert region is very different from that in a woodland region. In a more localized context, the factors of steep slope and deep drainage are generally significant, as well as the orientation of sunlight, and other topographical characteristics of the soil on the slope influence the assemblage of plant and animal that survive in the area of consideration.

The distribution of plants and animals are mostly determined by environmental factors slowly and gradually through time. However, occasionally, some catastrophic events become the determinant factor of biota. These abrupt elements include floods, earthquakes, volcanic eruptions, landslides, insect infestations, and droughts. Among these elements, causing complete or partial devastation of the flora and the killing or driving away of all or most of the fauna, wildfire is one of the most devastating environmental catastrophes.

These results are likely to be temporary; vegetation sprouts and animals return in the long run as the biota recovers from damage. However, at the least, the composition of the biota is changed in the short run, and if the fires occur with frequency, they may destroy the mutual relationship between preexisting biota and biome completely, and thus the ecological change may be inevitable. On a brighter side, wildfire can be helpful to the seeding or sprouting of certain plants and the maintenance of certain plant interactions. In some cases, natural fires are evaluated to sustain grasslands by preventing the encroachment of the tree seedlings.

Moreover, there are a variety of plant species that need the heat of a fire to make their seedpods to open and spread their seeds. All phenomena and biota on the Earth are intricately interwoven, and ecology with many facets is a way for us to observe the Earth system as a whole.

## economic geography

**KNOWLEDGE OF ECONOMIC** geography was first essentially descriptive, with a focus on the **REGION** and its economy, demography, and social characteristics. It represented the typical approach in research agenda in North America and Western Europe. The birth of economic geography dates from the age of European exploration, with an expansion in commercial geography from the 15th century to the 19th century. George Chisholm, author of the first book in economic geography, *Handbook of Commercial Geography* (1889), collected information on economic activity. In the late 19th century, economic geographers started to take into consideration the physical environment as influencing the economic activity.

The environmental determinist movement started with Ellen Churchill Semple's book (*The Influences of the Geographic Environment*, 1911), in which she explained how the environment is considered as a major factor in the location of human settlements and economic activity. The turn to the study of geographic regions gave birth to the areal differentiation movement in the mid-1930s, with Richard Hartshorne (*The Nature of Geography*, 1939).

The movement supported a geography that provided accurate, orderly, and rational descriptions and interpretations of regions. Economics has occupied a central position within human geography for more than a century, and started its modern development in

the 1950s. The post-1950s geography is characterized by the quantitative revolution.

The utilization of earlier location theoretic models by German spatial economists (Johann Heinrich Von Thünen, 1826; Alfred Weber, 1929; Walter CHRISTALLER, 1933; August Lösch, 1939) has contributed to the development of geography as a spatial science. The French economists, on their side, were working on the theory of **GROWTH POLES** and regional development problems.

Economic geography represents two areas very close to each other but with some nuances. It is referred first to as geographers working on spatial questions, with a synthetic approach from sociology, economics, political science, and history, reflecting the multidisciplinary character of the field of geography. Second, it is related to regional science with economists working on spatial mathematical models.

The work in the 1960s in quantitative geography was represented by William Alonso and Brian Berry. Alonso (*Location and Land Use: Toward a General Theory of Land Rent*, 1964), in the area of neoclassical economics associated with location theories was influential in urban land-use modeling. A William Alonso Memorial Prize was established in the United States by the council of the Regional Science International Association in 1999. Berry has worked, with his book *Geography of Market Centers and Retail Distribution* (1967), on market functions and spatial scale, focusing on settlement patterns and the hierarchy of places in national economies. Until the mid-1970s, with the main intellectual orientations of the neoclassical economics principles and of the German theorists, location has provided the new framework for the study of the spatial organization of the contemporary economy. Economic geography was, during the period, essentially an industrial geography dealing with the problems of industry and regional economic development.

The end of the postwar economic growth in major developed countries, the end of the golden age of capitalism, and the worldwide stagnation of regional and urban problems were all new questions for economic geographers. With the Marxist critique of capitalism, economics geographers switched their interests from neoclassical economics toward political economy, such as the Marxian political economy. David Harvey refocused his work toward a Marxist-based geographical political economy with his book *The Limits to Capital* (1982), which is still one of the best interpretations of Marx's work. From the mid-1970s to the mid-1980s, geographers dealt with the questions of regional and

urban problems, which included the logics and the dynamics of urban space, regional development and its crisis, the geographies of services, labor, and money, the restructuring of regional industries, and uneven development. Doreen Massey, with her book *Spatial Divisions of Labor: Social Structure and the Geography of the Production* (1984) on industrial restructuring, reacted to Harvey's abstract ideas by bringing a more concrete perspective of the place to the study of spatial relations.

From the 1980s on, economic geography has evolved in several field categories. Economic geography has taken a step toward critiques of the Marxist social and economic theory. This has led to a new turn in the development of capitalism, with the emergence of poststructuralist and postmodernist theories. Feminist geographers Katherine Gibson and Julie Graham, in their work *The End of Capitalism (as We Knew it): a Feminist Critique of Political Economy* (1996) on Marxist political economy, bring the concept of class as a central topic in economic analysis. They focus on the relationship between gender, social class, and economics and according to them, the discourse on Fordism and post-Fordism is too economic and male-centered.

## POSTMODERN PATHS

For Edward Soja (*Thirdspace: Journeys to Los Angeles and Other Real-and-Imagined Places*, 1996), postmodern ideas lead to a different path. The social complexity is originated from the importance of space and time. Influenced by Henri Lefebvre, Soja developed the model of the "Trialectic" of history, space, and society. He showed that spatiality, like history, is culturally produced, and that space is also a space of domination that is a representation of power and ideology.

Starting in the late 1970s, a turn to the resurgence of regional economies took place by economic geographers switching their interest from the areas dominated by the Fordist manufacturing activities to the high level of spatial agglomeration, including networking, innovation, and economic growth. Different schools of thought involving geographers, economists, and social scientists have emerged in works related to post-Fordism.

The first is represented by the Italian school with Giacomo Becattini (1987) and his colleagues at the University of Florence, who analyzed the Marshallian industrial district dealing with the location of new productions spaces. Three types of industrial districts were found: the local-, small-, and medium-enterprise net-

works in northeastern and central Italy, known as the Third Italy; the high-technology regional clusters in Silicon Valley, Orange County, and the highway 128 complex around Boston; and the London-Bristol axis.

The other school, the Californian school of geography, represented by Allen J. Scott, Michael Storper, and Richard Walker, and characterized by the study of industrial geography in southern California and the Bay Area, has a focus on flexibility in the division of labor in production. It also has analyzed agglomeration, including transactions costs associated with inter-firm linkages.

They recognized in the megalopolis or in the agglomeration some patchwork of districts. Although they had knowledge of regulation theory, their analysis was essentially based on neo-Marxism and neo-classical theories of labor division and the effects of external agglomeration. A third group can be discussed, the Groupe de Recherche Européen sur les Milieux Innovateurs (GREMI), created by Philippe Aydalot in 1986 and composed of geographers and economists studying new regionalism places such as Silicon Valley, Cité of Paris South, and Third Italy. The fourth is represented by Michael Piore and Charles Sabel, inventors of the concept of flexible specialization as a form of industrial organization in their book *The Second Industrial Divide* (1984).

According to the paradigm of Coase-Williamson-Scott that has emerged, industrial organization is always struggling between internal organizational costs in the firm and transactions costs between firms. Agglomeration of firms in a same location would minimize transactions costs, and thus be a factor in competitiveness. However, the flexibility of the production system has engaged new geographical dynamics, suggesting that networks of firms or smaller firms can respond more efficiently to changing consumer demands.

The Fordist spatial systems (vertical integration and spatial centralization) are less important and led the way to firms' agglomeration in search of minimal transactions costs. Michael Storper and Richard Walker, in *Capitalist Imperative: Territory, Technology, and Industrial Growth* (1989), have proposed a model of growth pole that has emerged in California. Allan Scott (1988) did a precise analysis of contemporary production systems, taking in consideration the social division of labor, transactions between the actors in the space of production, the different type of relations between the economic actors, and the role of political agencies. From the Italian district to world megalopolis,

the new paradigm of flexibility explains the return of production location and offices near urban areas and the revival of the quantitative growth of metropolitan cities. Geographers have analyzed the location of production, location of offices, space of logistics and distribution, organization, and locational choices and realized that the urban forms have changed compared to the postindustrial Fordist period.

Besides the ideas developed on districts and the evolutionists' approach to the diffusion of technological changes, another research idea has considered territory as an innovative milieu. The works on this topic have questioned the necessary external conditions that give rise to entrepreneurship and the adoption of innovation. Researchers do not consider that the firm is preexisting in the local milieu, but that the firm itself is created by them. Recent studies challenge the theories of industrial organization, industrial district analysis, and the evolutionist approach, which have been modified with the emergence and the diffusion of innovation. More emphasis has been put on the local milieu, the territory favorable to innovation.

### FRENCH SCHOOL

All the approaches described above, even if they do have common questions, do not converge on post-Fordism and the effects of milieu. For example, Danielle Leborgne and Alain Lipietz (1992), in their works on the institutions of social regulation and the forms of relations among firms, found the model of Marshallian district is not so important and is regulated by a combination of commercial relations and a reciprocal atmosphere. The French "regulation" school of Michel Aglietta and Alain Lipietz worked on the regulation theory to provide an understanding of the capitalist mode of production and its instability. It attempted to theorize the social and economic relations that support economic growth (accumulation). The functioning of the accumulation regime is deeply affected by the state and financial institutions that have an impact on the markets forces.

The French regulation theory has been very influential in explaining the transition in capitalism from a Fordist regime of accumulation and regulation to a new post-Fordist regime. Ash Amin (1994) applied the regulationist ideas to geography and proposed that the mass-production Fordist regime of accumulation has led to a post-Fordist regime. Piero Sraffa also contributed to economic structure and a linear production model has been influential in economic geography with Sraffa's book *Production of Commodities by Means of*

*Commodities: Prelude to a Critique of Economic Theory* (1960).

### LEONTIEF'S MODEL

Sraffa's model is a formalization of Marxian ideas of value/price and wage/profits relationships, and his model is identical to the input-output model of Wassily Leontief. The Leontief model influenced research on regional growth and the study of impact analysis developed by Walter Isard and Richard Stone. The neo-Marxian geographers integrated the Sraffa models in their model of capitalist crisis. Eric Sheppard and Trevor J. Barnes (*The Capitalist Space Economy: Geographical Analysis after Ricardo, Marx, and Sraffa*, 1996) studied the capital-labor conflict and showed that, when it is combined with the spatial interpretation of industrial cost and residential location, it explained the patterns of urban settlements, technological change, industrial organization, restructuring, and monopoly power. Michael Webber and David Rigby, in *The Golden Age Illusion: Rethinking Postwar Capitalism* (1996), mentioned that since the Sraffa-based spatial model already contains the possibility of an endogenous crisis because of the technological competition and the decline of the productivity, the regulationist ideas of decline of capitalism were not useful.

The rise of new technologies and new forms of economic organization lead toward profits and productivity growth. The new rise of competition in a global economy and the breakdown of the Bretton Woods system have been the driving force in this post-Fordist change of economy and geography. Network and governance are two key economic concepts that appeared in the 1990s.

Economic and geographical works have focused on the organization of the relation between unit production and its spatial development. In this area, a network is called the spatial dimension of regulation between productive units; moreover governance is the regulation mode of those relations which are in different forms: hierarchical, sub-contracted, or partnerships. Michael Storper and Bennett Harrison showed the great diversity of the governance mode that they take into consideration only if it organizes the inter-firms relations. It is a complex theory that comes from the domain of industrial organization, labor division, institutions and conventions, and the possible locations resulting from the modality of governance.

Spatial economists have elaborated on a new economic geography, which is a reflection of their increasing interest in the concept of space. This represents a

One aspect of economic geography studies the spatial distribution of financial resources in a given context. The graphic analysis of gross domestic product per capita above shows how productivity and income are distributed around the world.

recent tendency to add “new” to the term *economic geography*, particularly since the work of the MIT economist Paul Krugman (1991) entitled *Geography and Trade*. He took into consideration, for example, the role played by distance and place in international trade. Krugman tried to show how exchanges in a country are affected by the process of geographic industrial specialization and, in return, how the process can influence further exchanges.

In a slightly different perspective, for the business economist Michael Porter (1990), the geographic con-

centration of industry in a national economy plays an important role in the determination of sectors that have a competitive advantage within the international economy. The new economic geography adds to regional economics with specific modeling approaches.

Krugman has contributed to several topics relating to the problems of regional development, exchange, externality, industrial location, strategic industrial policy, and the consequences of the economic integration and monetary policy on regional growth. He has used several economic and geographic theories, taking into

consideration the locational economics of Alfred Marshall, cumulative causality, and traditional theories of location. The geographical emphasis by Krugman and others has been criticized because of their modeling of space that is too narrow; their interest is in the description of abstract space and not in a specific place.

The 1980s and the 1990s have been marked by works on the metropolis. The city has been studied from the angle of the production system, with the apparition of the post-Fordist city concept. Globalization has certainly transformed the structure of urban societies. John Friedmann has established a world urban hierarchy using the location of headquarters and decision centers of corporations and international organizations. It is an extension of the theory of urban hierarchy that affirms that the geographical deployment of multinational companies is a function of the transactions done by the companies. The problem of globalization is an important topic for economic geographers, particularly since the increase in multinational corporations operating at a global level but also because of a new movement in capital. In effect, capital becoming more mobile.

### GLOBAL INFORMATIONAL CAPITALISM

Manuel Castells, in his three volumes, provides an interesting and complete analysis of global informational capitalism (1996, 1997, and 1998). Castells emphasized the role of information and telecommunication, leading to the territorialization of the economy and society, and he developed a new spatial logic called the space of flows. The flows are structured in networks dominated by big companies and by managerial elites. Information is the key input of the world economy for the formation of capitalist agglomeration. Information, new technologies, and restructuring in the capital-labor relation induce the emergence of new urban forms. Thus, the informational city is on the rise.

Saskia Sassen (*The Global City: New York, London, Tokyo*, 1991) developed the concept of the global city. She showed that globalization can be seen only in some cities, such as NEW YORK, LONDON, and TOKYO, where banks, corporate headquarters, and high-level functions are strategically concentrated. Decisions made in these global cities can affect jobs and wages, but also the conditions of the economy in more remote location such as in MALAYSIA, CHILE, or other places. The three cities are global because of the structure of their activities (industries and international services), the qualifications of the labor force, and relative productivity.

Globalization as an economic and geographical phenomenon that has gained interest from geographers. The origin of this interest comes from the older geographic research on the international division of labor and the activities of multinational corporations. Moreover, the region as a source of competitive advantage in the globalization process of the economy, has received special study (Porter, 1990, 1998; Saxenian 1994; Scott, 1998). Another characteristic of globalization is the dual structure of society, in which there are elite with high incomes living side by side with poor workers. Global cities have accumulated wealth, decision centers, research laboratories, and financial centers. But such growth is accompanied by a decline in some economic sectors, degradation of vast urban areas, structural poverty, and chronic insecurity. At the international level, there is a consolidation of socioeconomic geography, which involves economics and the social components of space. Studies of post-Fordism, innovative milieus, industrial districts, governance, local production systems, and the economy of proximity are increasing.

Globalization, with its creation of borderless markets, mobility of finance, transnational firms, and an information economy has signaled the “end of geography” (Richard O’Brien, 1992) and the “death of distance” (Cairncross, 1997). According to some these theorists, globalization is rendering the location of economic activities less relevant.

For others, globalization is increasing the importance of location and that is promoting regional economic distinctiveness. Spatial clustering, a concept at the core of economic geography, has been developed to explain the advantages of being in the same place as others to generate economic processes.

Recently, economic geographers became interested in telecommunication technologies and the changes brought on by the internet. These studies are represented by Stephen Graham and Simon Marvin in *Telecommunication and the City* (1996), Rob Kitchin in *Cyberspace* (1998), Manuel Castells in *Internet Galaxy* (2001), and Graham and Marvin in *Splintering Urbanism* (2001).

The boom of the new economy based on the information technology and the internet came to end with the economic downturn in 2001. But geographers, such as Thomas Leinbach and Stanley Brunn (*Worlds of E-Commerce: Economic, Geographical and Social Dimensions*, 2001), have just begun to analyze the relationships of virtual spaces of telecommunication networks and conventional geographic spaces.

Globalization and global cities, such as New York, are central to the study of economic geography today.

The end of the 1990s brought a change in internet distribution methods, with e-commerce heralding a new digital economy. However, commercial transactions, even on a global basis, still depend on the management of the logistic side of geographic space and time. Into the 21st century, a new era of profound economic change emerged with strong implications for economic geography. Economic geography will continue to focus on aspects relating to change in the human economic system.

## ecosystem

THE CONCEPT OF the ecosystem began with the establishment of the science of ecology which is credited to Ernst Haeckel, a German zoologist who coined the term *ecology* in 1869. He based this term on the Greek word *oikos*, meaning “a place in which to live.” It was another 60 years before the term *ecosystem* was introduced in 1935 by Sir Arthur Tansley, a British ecologist and supporter of environmental conservation.

In a classic publication in the journal *Ecology*, Tansley defined ecosystem: “The more fundamental conception is the whole system including not only the organism complex, but also the whole complex of physical factors forming what we call the environment. We cannot separate them (the organisms) from their special environment with which they form one physical system. It is the system so formed which provides the basic units of nature on the face of the Earth. These ecosystems, as we may call them, are of the most various kinds and sizes.”

Thus, an ecosystem comprises a group of coordinated components of the environment; such components may be biotic, that is, relating to life such as plants, animals, humans, or abiotic, that is, relating to non-living components of the environment such as water, soil, climate. All ecosystems are organized and structured; the biotic and abiotic elements and the links between them can be identified and in many cases quantified. All ecosystems function via the relationships between the components. Their natural state is one of dynamic equilibrium whereby a balance exists between the components that is maintained through negative feedback or self-regulation. Thus, the character and functions of the ecosystem prevail.

If imbalance occurs, because of an external stimulus such as climatic change or an internal agent such as human activity, positive feedback will occur. Alterations in the components and their functions occurs until a new equilibrium, that is, an ecosystem with dif-

ferent characteristics from the original, is reached. The reaction of ecosystem components to positive feedback is rarely immediate because of inherent resilience to change, which takes time to overcome. Consequently, most stimuli will generate a lagged response as thresholds of resistance are overcome. Moreover, ecosystems may be defined at any scale. At one end of the spectrum is the Earth itself, or more specifically the biosphere, which is the zone adjacent to the Earth's surface where all life exists, and at the other end of the spectrum is a small pond. Ecosystems are open systems insofar as they can be influenced by external factors and there may be imports and exports of mass and energy.

One ecosystem function involves the cycling of chemical elements and compounds. This movement of chemicals between the biota, soils, oceans, and atmosphere is biogeochemical cycling. Each chemical has several major pools or reservoirs between which fluxes or exchanges occur. If the atmosphere is involved, the biogeochemical cycle is described as gaseous, but if there is no atmospheric component, the cycle is considered to be sedimentary. Carbon, nitrogen, hydrogen, and oxygen (the latter two are combined as water) have gaseous biogeochemical cycles, as they all have significant reservoirs in the atmosphere.

Moreover, the volumes of these elements, especially carbon as carbon dioxide and methane, in the atmosphere influence climate. Thus the Earth's biotic and abiotic components are arbiters of climatic change which in turn affects the distribution of the biota and the functions between the biota and abiota. Examples of sedimentary biogeochemical cycles are those of phosphorus, calcium, sodium, and magnesium in which the major reservoirs are the biota and soils between, with fluxes operating through the medium of water.

Another major function within ecosystems is energy flow. It is quite essential for life and involves the harnessing of solar energy which, despite the sophistication of human society, can be achieved only by green plants. All animals, including humans, are dependent on this function. Called photosynthesis, this is a complex biochemical process undertaken by terrestrial and aquatic plants that contain chlorophyll. Carbon dioxide and water are combined in the presence of solar energy to produce carbohydrates, which are a source of energy for the plants and from which all other plant components are manufactured. The efficiency of photosynthesis depends on water, nutrient, and light availability. This manufacture of carbohydrates is known as primary productivity.

Plants are the first stage in energy transfers in ecosystems, while the second stage involves food chains and food webs. Animals feed on the primary producer plants and other animals feed on these primary consumers. Humans are omnivores and feed on both plants and animals mostly produced in agricultural systems which are essentially intensively managed ecosystems.

## ECOWAS

THE ECONOMIC COMMUNITY of West African States (ECOWAS), also known in French as Communauté Économique des États de l'Afrique de l'Ouest (CEDEAO), was first formally set out at the Monrovia Group meeting in April 1968. By the Treaty of Lagos, 15 representatives from West African states formed ECOWAS in Lagos, NIGERIA, on May 28, 1975. These were: BENIN, BURKINA FASO, CAMEROON, CÔTE D'IVOIRE, GAMBIA, GHANA, GUINEA, GUINEA-BISSAU, LIBERIA, MALI, NIGER, Nigeria, SENEGAL, SIERRA LEONE, and TOGO. CAPE VERDE later joined the community making it a 16-member economic organization. Based on their colonial experience, three official languages are spoken in West Africa: English, French, and Portuguese.

The principal objective of the treaty is the creation of an economic and monetary union. To this end, a regional trade liberalization scheme was adopted for the creation of a free trade area at the end of 1999, and a common external tariff is being implemented in phases. The three-phase program for the free movement of ECOWAS citizens has been completed. ECOWAS has pursued the physical integration of its member states through the modernization of regional highway and telecommunication networks.

ECOWAS became effective in July 1975, when the necessary seven states ratified the treaty. The first meetings of the Council of Ministers and the Authority of Heads of State and Government took place in Lomé, Togo, in November 1976, at which time additional

protocols to the treaty were signed. In July 1993, the 16 West African heads of state signed a revised treaty, reflecting West Africa's regional cooperation experiences over the preceding 15 years, and taking into account the exigencies of continental integration as envisaged in the Treaty of the African Economic Community.

Member states committed themselves to coordinating and harmonizing varied national economic and financial policies in order to enhance the effectiveness of national structural adjustment and economic reform programs. The ultimate goal is to facilitate the regional approach to economic development and the establishment of the monetary union. The monetary program adopted by ECOWAS has the medium-term objectives of achieving regional convertibility of the nine national currencies and, in the longer term, the creation of a single monetary zone. Meanwhile, an ECOWAS traveler's check was launched in October 1998 to facilitate regional travel and commercial transactions.

### UNIFORM CURRENCY

As part of efforts to realize its uniform currency and monetary system, a West African Monetary Institute (WAMI) became operational in January 2001. The two-year transitional body is based in Accra, Ghana. There is also a Committee of Governors of West African Central Banks that has been coordinating the implementation of the ECOWAS monetary program through the West African Central Bank. A uniform currency was scheduled to come into effect in 2004.

In addition, ECOWAS is embarking on such programs as the interconnection of national electricity grids; a regional pipeline for the distribution of natural gas; community seed production and cattle breeding centers; agricultural research; a regional master plan for industrial development; coordination of desertification control; rural water supply plans; cooperation in health matters; and establishment of equivalence for degrees and diplomas.

In the treaty, particular emphasis is placed on promoting the involvement and participation of the private sector and the general public in the development and integration of the economies of the region. ECOWAS encouraged the establishment and functioning of a privately owned regional commercial bank (ECOBANK), as well as the Federation of West African Manufacturers Associations, Federation of West African Chambers of Commerce, West African Journalists Association, West African Youth Union, West African Women's Association, West African Road

Transporters Union, and others. ECOMOG was created to act as peacemaking apparatus for member countries.

The Authority of Heads of State and Government is the supreme organ; it has a rotating chairmanship and meets at least once a year. The Council of Ministers comprises two representatives from each member state and also has a rotating chairmanship. It meets at least twice a year; decisions are made by a consensus. The Executive Secretariat is headed by an executive secretary appointed for a four-year term.

There are also five specialized commissions dealing with different aspects of cooperation. Provided in the treaty is a Court of Justice to ensure “the observance of law and justice, to interpret the provisions of the Treaty, and to settle disputes referred to it.” The seven justices for the court, which is based in Abuja, Nigeria, were sworn-in in January 2001 in Bamako, Mali. The treaty provides for a West African Parliament, inaugurated in Bamako, Mali, on November 16, 2000.

## Ecuador

**Map Page** 1139 **Area** 109,483 square mi (283,560 square km) **Population** 13,212,742 (2004) **Capital** Quito **Highest Point** 20,561 ft (6,267 m) **Lowest Point** 0 m **GDP per capita** \$3,300 **Primary Natural Resources** petroleum, fish, timber, hydropower.

ECUADOR IS A SMALL country located on the west coast of South America. The equator crosses the country, thus giving Ecuador its name. The country is bordered by the PACIFIC OCEAN to the west, COLOMBIA to the north, and PERU to the east and south. Territorial

disputes with both Colombia and Peru have reduced Ecuador's territory.

The Pacific coastal zone, mainly an ALLUVIAL PLAIN, consists of 60,000 square mi (155,399 square km) of land between the ANDES MOUNTAINS and the Pacific Ocean. These lowlands form the widest coastal plain in South America, reaching widths of 125 mi (201 km). While there are some hills, the region is largely flat. The northern coastal region is largely RAINFOREST, while the south consists of tropical woodlands. The region contains a number of important river valleys. Some of the rivers are navigable for long distances, with the basins of the Guayas, Esmeraldas, and Santiago rivers creating an extensive inland waterway network.

The key area of the coastal zone is the Guayas Lowland, where much agricultural production takes place. This agricultural production is geared to the export economy. The main crops include cocoa, coffee, bananas, and rice. Others regions of the coastal lowlands are used for fishing and cattle raising. Ecuador has also exploited oil reserves in the coastal region. Thanks to the presence of such resources, the coast has long dominated the economy of Ecuador.

The main city of the lowlands is Guayaquil, located on the western bank of the Guayas River. Guayaquil is an important port and commercial center, serving as an outlet for the region's products. It is also the country's largest city.

Known as the Sierra, the Andean highlands of Ecuador make up about one-fourth of the country's territory. These highlands are made up of two cordilleras, or ranges. The Ecuadorian Andes are narrow but high, averaging an altitude of over 10,000 ft (3,048 m). The ranges consist of high, snow-topped, volcanic peaks. The highest peaks are Chimborazo, which reaches an altitude of just over 20,000 ft (6,096 m), and Cotopaxi, which is just under 20,000 ft. In addition to dozens of volcanoes, the region is also subject to strong earthquakes. For example, an earthquake in 1797 completely destroyed the city of Riobamba, forcing survivors to rebuild at a new location.

A 300-mi- (483-km-) long intermontane plateau is located between the eastern and western ranges. Transverse mountains divide the plateau into 10 basins at elevations between 7,000 ft (2,133 m) and 10,000 ft (3,048 m). The basins fall into one of four climatic zones. The area above 10,065 ft (3,246 m) is known as *páramo*, which is barren and windswept. The *páramo* is generally used for pastureland and to grow potatoes, a crop native to South America. At elevations of 8,052

ft (2,454) to 10,065 ft (3,246 m) is the altiplano, used for both pasture and growing grains. Temperate valleys can be found at altitudes from 6,039 ft (1,840 m) to 8,052 ft (2,454 m). Temperate crops are grown in these valleys. Finally, from 3,018 ft (920 m) to 6,039 ft (1,840 m) are tropical valleys, where in addition to potatoes and grains, Ecuadorians grow cotton, sugarcane, and fruits.

This plateau forms the densely populated heart of Ecuador and has historically dominated the country. Pre-Hispanic cultures centered here and the Spanish preferred the Andean plateau over the coastal zone. Quito, the capital city, is located in the plateau at 9,350 ft (2,850 m). The region contains a large percentage of Native Americans and mestizos (mixed race).

The hot and humid eastern lowlands of Ecuador are known as the Oriente. This region comprises about half of the country's territory. The Oriente has often been at the center of territorial disputes, and Ecuador has lost large sections of this region to its neighbors. It covers the area stretching from the eastern foothills of the Andes to the AMAZON RIVER basin. Much of the Oriente is a FLOODPLAIN covered with tropical woodlands and rain forests. There are navigable rivers in the region. However, they generally flow away from the settled areas, making them of limited use.

Historically, the Oriente has been isolated, underdeveloped, and sparsely populated by humans. Before the 1960s, both settlement and investment in the region were very limited. Ecuadorian authorities paid attention to the area only when border disputes arose. The fact that most of the population consisted of Native Americans further contributed to government neglect.

Heavy rainfall has made human settlement unattractive, as dry land shrinks during the rainy season, wild game is scarce, and agriculture is difficult. In the northern Oriente, annual rainfall can reach 167 in (424 cm). After the 1960s, the government became more interested in the Oriente due to the discovery of significant oil deposits. High world oil prices in the 1970s led to increased investment in the region.

Ecuador is also home to the famous Galápagos Islands, where Charles Darwin conducted experiments there in 1836 leading to his evolutionary theories. Known as the Archipelago de Colon, the Galapagos Islands consist of five larger islands and nine smaller ones.

The islands are located in the Pacific Ocean about 600 mi (965 km) west of the mainland. Their total area is just under 3,000 square mi (7,770 square km) and

there are few inhabitants, most notably because potable water is scarce.

## Egypt

**Map Page** 1114 **Area** 622,272 square mi (1,001,450 square km) **Population** 70,712,345 (2002) **Capital** Cairo **Highest Point** 8,625 ft (2,629 m) **Lowest Point** -436 ft (-133 m) **GDP per capita** \$3,700 **Primary Natural Resources** cotton, rice, corn.

EGYPT HAS BEEN a unified state for more than 5,000 years and is one of humanity's oldest civilizations of great political systems and unique art and architecture. Centered on the NILE RIVER, which drains the uplands of East Africa, early Egyptians worshiped the river that brought seasonal flooding and sediments to its river valley, annually rejuvenating its fields and orchards.

As the most populated country in the Arab world, most of its 70 million residents live in Cairo and Alexandria, the river delta and valley, and along the Suez Canal. The remaining desert villages are associated with isolated oases and caravansary routes. The government has repeatedly tried to entice residents to move from the dense cities to rural settings; however, Egypt's cities have continued to grow.

The population density of Cairo (al-Qahirah) is the highest in the region and is exceeded globally only by mega-cities like HONG KONG, NEW YORK CITY, and MUMBAI. With more than 350,000 people per square mile (136,000 per square km) and a total population of more than 15 million residents, Cairo is bustling city of luxurious skyscrapers and tin hovels, separated by zigzagging passageways and broad boulevards, all cramped with buses, tourists, cars, vendors, taxis, busi-

nessmen, and occasional fruit-filled carts. It is a city of dichotomies, with discos and mosques, fruit stands and department stores side by side, all divided by the Nile, the world's longest river during the rainy season.

Once beyond the lush fringe of the Nile, the arid lands of Egypt are formidable. The harsh land is occupied by native Bedouins and undaunted explorers and researchers. Daytime summer temperatures in the western desert can reach 130 degrees F (55 degrees C) with relative humidity as low as 5 percent. Perpetually battered by the SAHARA DESERT's desiccating winds, climatologists consider it one of the driest lands on Earth.

Although its desert interior is hyper-arid, Egypt's delta is lush, humid, and productive. Ninety percent of Egypt's agriculture is confined to 3 percent of the land: the delta and the narrow belt that lines the MEDITERRANEAN SEA and the Nile River from Cairo to Aswan. Because of its increasing population and small farmlands, Egypt must import increasingly more vegetables and fruits, although agriculture remains an important sector of the economy, contributing 14 percent to the GDP and employing nearly 30 percent of the total employed population. Despite this land of extremes—very rich to destitute, very humid to hyper-dry, open deserts to cramped suburbs—Egypt remains famous for its cheerful and generous people, whose hospitality is as legendary as its pyramids.

Since Egypt's earliest known ruler Menes created the first pharaonic dynasty in 3100 B.C.E., Egypt has continued to exert power throughout the region. As the kingdom expanded, monumental pyramids and temples were built, and repeated raids by Persians, Greeks, and Romans changed Egypt forever. Influence shifted from Memphis to Alexandria in 322 B.C.E. under Alexander the Great and became a mighty force on the Mediterranean Sea. The Ptolemaic rulers (like the renowned pair of Cleopatra and Marc Antony) guided Egypt until it was conquered by Arab marauders in 643 C.E. and converted into an Islamic state.

Following the Arab invasion and a transfer of power to Cairo as its new center, Egypt was controlled by a series of Arab, Mamluke, and Ottoman caliphs, sultans, beys, and pashas. Ottoman Turks ruled from 1517 to 1882, with a brief interruption by French rule under Napoleon Bonaparte at the end of the 18th Century. Mohamed Ali, an Albanian officer in the Ottoman Army, was appointed pasha in 1805 and founded a dynasty that ruled the region, built the Suez Canal, and modernized Cairo. In 1952, the great-great grandson of Mohamed Ali, Farouk I, was defeated. However, it was after a skirmish with Ottoman troops

in 1882 that the British successfully occupied Egypt until the kingdom declared its independence from England in 1922. The Egyptian government nonetheless, remained codependent on English ways and endured their use of Egypt for bases of operations during World War II.

In 1948, Farouk was blamed for the loss in the war with the newly created state of ISRAEL, leading to his defeat during a military coup led by Colonel Gamal Abdel Nasser in 1952. Nasser's charisma complemented his strong leadership skills and a new brand of regional socialism. After his death in 1970, Anwar al-Sadat served as president until his assassination in 1981. Strong ties were forged between Egypt and other nations during this period, including the Soviet Union, which supported the two-year construction of the Aswan High Dam (Sa'ad al-A'ali) and the impoundment of Lake Nasser in 1970.

After Sadat's assassination by Islamic radicals, an Egyptian Air Force commander, Hosni Mubarak, was elected president. Into the 2000s, he has continued to support a number of Middle East peace accords, and his attempts to increase private sector involvement and investment in Egypt have proved successful so far. Mubarak has since been reelected three times, continuing to deal with national concerns of poverty, crime, overpopulation, and poor water resources.

## El Niño and La Niña

EL NIÑO AND La Niña are parts of global weather systems that recur every two to seven years. An El Niño, which usually lasts 12 to 18 months, is characterized by warm winters and wet springs in North America, a lessening of monsoonal rains in Asia, and droughts affecting Africa and the south PACIFIC OCEAN. A La Niña system follows for up to three years, producing opposite effects.

Southern Oscillation indicates the variations in sea level pressure noted in the Pacific between the southern and northern hemispheres. Both El Niño's and La Niña's are considered part of the El Niño Southern Oscillation (ENSO), a term used to describe the full range of wind and ocean patterns reflected in the Southern Oscillation itself. An El Niño occurs when the northeast tradewinds of the south Pacific slacken, and in the same area, ocean water warms and moves east. This action can reverse the trade winds by causing an increase in warm air, which rises and changes air pressure patterns. Abnormally dry weather then settles over islands in the tropical Pacific like INDONESIA, BORNEO, and the PHILIPPINES, while humid, warm air affects the west coast of South America.

Over several months, an El Niño impacts world weather patterns. In winter, the U.S. Pacific northwest and western CANADA get less rain, while southern CALIFORNIA and the Gulf Coast experience more rain and storms. Also in the UNITED STATES, warmer temperatures affect the Great Plains and upper midwest. BRAZIL, southern Africa, and AUSTRALIA experience dryness and drought. Rainfall lessens and drought often hits INDIA and southern Asia. Monsoonal moisture, a critical element on which all farmers depend, may not arrive, and the result is famine, often followed by diseases and death. Fewer hurricanes develop in the ATLANTIC OCEAN, and less rain falls in MEXICO and the southwestern UNITED STATES. In the Pacific Ocean, more typhoons occur.

Clearly, aberrations in the weather can cause great hardship and loss of life. The loss of monsoon rains in India for several years in the 1890s caused a famine that claimed over 4 million lives. An El Niño brings other troubles as well: Abnormal ocean temperatures keep fish from shore, ruining coastal economies. Normally dry high altitudes get snow, and months later when the snow melts, mudslides and flooding can follow. Huge brush fires, sparked in unusually dry conditions, can devastate large areas; in 1997 and 1998, fires in Indonesia caused at least \$9 billion in damage and lost timber, as well as dramatically polluting the air throughout Southeast Asia to such an extreme extent that the sun could not be seen for days in some cities. Even when the fires were extinguished, underground peat continued to burn, contributing to the pollution.

An El Niño is typically, but not always, followed by a year or more of La Niña conditions. During La Niña, also called an El Viejo, the temperatures in the equatorial Pacific region are colder than normal. This results in wet winter weather in the South Pacific and

southern Asia, and drier conditions along the South American coast. In the United States, winter temperatures are warmer in the southeast and cooler in the northwest.

The history of the ENSO goes back thousands of years, but it was not identified until recently. In 1891, the president of the Lima Geographical Society first officially reported that fishermen in PERU sometimes noted a warm countercurrent in the Pacific Ocean right after Christmas that indicated more rain, exotic fish, and lots of vegetation would come the following year. The locals called it El Niño, a term referring to the Christ child. Although droughts, floods, and seasons of unusual weather had been noted and even studied for years, it was not until the 1920s that scientist Gilbert Walker identified the Southern Oscillation. In the 1960s, Norwegian meteorologist Jacob Bjerknes connected Walker's discovery with the extensive ocean warming of an El Niño system. He described the anomalous circulation patterns that followed, and named them the Walker Circulation.

Scientists, historians, archaeologists, and researchers all over the world are now putting events and data together, realizing that weather systems such as the ENSO last for years and have impacted civilizations on a global scale for millennia. Events once considered random and unrelated are now being explained in terms of climatic events. El Niño droughts were likely responsible for the downfall of the Mayan civilization in Central America, the Moche Empire of Peru, and the Anasazi complex of the American southwest. Glacial ice cores, coral reefs, and tree rings provide evidence of ancient weather patterns and anomalies.

The El Niño of 1997–98 was one of the worst in recent memory. The fires of Indonesia have been mentioned; large economic losses impacted many areas, such as Australia and Southeast Asia, where drought occurred. Ironically, this El Niño came with much advance warning, and areas like heavily populated California were able to invest millions of dollars in preparation, thus avoiding more losses.

Groups such as the National Oceanic and Atmospheric Administration (NOAA) predict and track El Niños using satellites, research ships, buoy arrays, computer modeling, and other tools to analyze ocean temperatures, wind speeds, fish populations, precipitation, and other early indicators of developing weather systems.

## El Salvador

**Map Page** 1136 **Area** 8,108 square mi (21,000 square km) **Population** 6,470,379 **Capital** San Salvador **Highest Point** 8,956 ft (2,730 m) **Lowest Point** 0 m **GDP per capita** \$4,600 (2002) **Primary Natural Resources** coffee, sugar, corn, rice, beans.

THE REPUBLIC of El Salvador is located on the PACIFIC OCEAN in Central America, between GUATEMALA and HONDURAS. It is the smallest Spanish-speaking nation in the Western Hemisphere. The country is a democratic republic with a strong executive branch, a unicameral legislative assembly, and a supreme court. For administrative purposes, the country is divided into fourteen departments, which all together make up a territory slightly smaller than the state of MASSACHUSETTS.

Having gained independence from SPAIN in 1821, El Salvador developed slowly but remained reliant upon its cash crop economy and monoculture based upon coffee sales. The country was also war ravaged throughout the 1980s and into the 1990s by a 12-year civil war that completely destabilized the country and claimed an estimated 75,000 lives. Finally brought to a close in 1992, when the conservative government signed a political reform agreement with leftist rebels, the end of the civil war did not automatically result in progress.

More recently, El Salvador has suffered two major natural disasters: Hurricane Mitch in 1998 and a strong earthquake in 2001, both of which brought the country to a standstill. More positively, inflation has finally dropped to single-digit levels recently and exports

have grown significantly, even though world coffee prices remain relatively low. El Salvador has a massive trade deficit, but the majority of it is offset by the tremendous amount of remittances sent back to El Salvador by its citizens living in the UNITED STATES, which amounts to over \$2 billion annually.

### EARTHQUAKES

Geologically, El Salvador rests atop one of the most active tectonic plates, resulting in a high frequency of earthquakes and volcanoes. The country has suffered a long history of earthquakes, consequential in the recorded destruction of the capital city in 1756, 1854, 1919, 1982, 1986, and more recently, in 2001. Two of El Salvador's 20 known volcanoes are active, known as Miguel and Izalco, but violent eruptions are rare. In fact, their eruptions are often enjoyed from safe distances by viewers who awe at the glowing lava that slowly turns into a brilliant luminous color during the night after a minor eruption. The glow from the Izalco volcano has earned the mountain its nickname as the "Lighthouse of the Pacific."

Two mountain ranges cross the country from east to west and a central plateau rests between them, while a very thin area of coastal plains is found along the Pacific Ocean. The northern range, known as the Sierra Madre, forms the border with Honduras. Once heavily forested, the region has been irreversibly damaged by logging and agriculture. The southern range is actually a chain of clustered volcanoes. The central plateau in between is home to a majority of the country's population and the largest cities.

The country's only navigable river, even though it has over 300, is the Rio Lempa, which flows out of Guatemala, through the central plateau, and cuts through the southern mountains, eventually emptying into the Pacific Ocean.

El Salvador's climate is tropical with clearly distinguishable wet and dry seasons. Temperatures vary by altitude only and not by season. The Pacific lowlands are often unbearably hot, while the highlands and central plateau are more moderate.

## Elbrus, Mount

MOUNT ELBRUS IS the highest point in Europe, at 18,513 ft (5,642 m). It is the central peak of the CAUCASUS MOUNTAINS range, located 6.8 mi (11 km) north of the main ridge that forms the boundary between GEORGIA and RUSSIA, thus placing the mountain within Europe, since the traditional dividing line between Asia and Europe is along the main ridge of the Caucasus. The closest large town is Tynyauz, in the autonomous region of Kabardino-Balkaria, while the largest city with air and rail links is the Russian city of Pyatigorsk, 62 mi (100 km) to the north.

Elbrus is an extinct minor volcano that retains its conical shape characteristic of volcanic peaks. There are two summits, which are actually quite close in elevation. The lower summit (to the east) is only 72 ft (21 m) lower. In between the two, the area known as the Saddle has an elevation of 17,769 ft (5,416 m). Other notable features are the Pastukhov Rocks, at about 15,400 ft (4,700 m). The snow line in August lies at about 11,483 ft (3,400 m), above which the mountain supports a permanent icecap and 22 glaciers that covers about 56 square mi (144 square km). The runoff from these glaciers feeds major rivers, including the Baksan, Kuban, and Malka, flowing either west to the Sea of Azov, or east to the CASPIAN SEA.

Mount Elbrus was known to the ancient Greeks (called Mount Strobilius) and was the setting of the myth of Prometheus, chained to a rock atop this peak as punishment for bringing fire to humanity. Mountaineering became popular in the region from the late 19th century, accelerated by the first successful ascent to the top in 1874, followed by state sponsorship by the Soviets in the 1930s.

The mountain became one of the symbols of communist society's dominance and control of the wilds of the natural world. Since then the sport has only increased in popularity, resulting in frequent crowds of rock climbers. Visitors use cable car systems built in the 1960s, from the nearest mountain villages (Azau, Cheget and Tershol), located at about 6,560 ft (2,000 m). The cable cars extend to 12,450 ft (3,800 m), after which the ascent to the summit is nearly vertical.

## Elburz Mountains

THE ELBURZ (or Alborz) Mountains are a narrow mountain range that curve along the southern shore of the Caspian Sea in the north of IRAN. From west to east, the range measures about 600 mi or 970 km long. The Elburz range forms a climatic barrier between the Caspian and the Central Iranian Plateau. The northern side receives a good deal of snow and rain and is blanketed by lush forests and a fertile coastal plain. The southern side, in stark contrast, has few trees and is characterized by barren brown slopes and desert below.

The Elburz Mountains and their neighboring range to the east, the Kopet Dag, were originally volcanic. They retain the verticality typical of this origin and rise almost as a sheer wall from the southern shores of the Caspian Sea. As relatively recent formations, the Elburz range is among the highest in the region and includes Iran's highest point, Damavand (18,934 ft or 5,771 m). Elburz was important in Persian mythology as a remote resting place of heroes and gods. The abrupt south face of Mount Damavand (Demavend, or Dem Âvend Kuh) towers over the city of Tehran. Other highest peaks are Alamkuh and Takht-i-Suleiman, both above 14,850 ft (4,500 m). The average peak height is 9,000 ft (2,730 m).

Numerous subordinate parallel ridges enclose fertile valleys. The main navigable river that passes through one of these and into the CASPIAN SEA is the Kizil Uzen, which joins with the river Shah south of the range, then cuts a gap through the western end of the range. This gap divides the Elburz Mountains from the Talish Mountains to the north. On the northern side of this gap, the combined rivers are known as the Safid in the few kilometers before it reaches the sea. Smaller seasonal rivers that drain off the southern slopes of the Elburz disappear through evaporation in Iran's northern Salt Desert. At the foothills of the Elburz is the most significant Iranian port on the Caspian, Bandar-e Anzali, the center of the Iranian caviar industry. It is connected to the larger city of Rasht, the terminus of rail and oil lines. At the other end of the range, the city of Bandar Torkoman lies near the frontier with Turkmenistan and has long been a trade and communications ENTREPOT between the MIDDLE EAST and Central Asia.

## electoral geography

ELECTORAL GEOGRAPHY is a part of POLITICAL GEOGRAPHY. It is the geographical study of political space in democratic states. Electoral research in dictatorships can be useful although, their citizens are not really freely choosing. Electoral geography is therefore a special study of electoral processes and districts to map election results and then to test the results for the causes. Electoral geography as the study of election districts and the voting behavior in them has been of interest to politicians, political scientists, geographers and others since the rise of democracies in place of other forms of government in the last several centuries.

In England before the American Revolution and in the UNITED STATES since the adoption of its present constitution the practical politicians who have had the power to shape legislative districts have found that the boundaries of districts can be drawn to favor one political party over another. The American term for this is *gerrymandering*. The term was first applied to election districts drawn in the late 1700s in MASSACHUSETTS by the Federalist Party. At the time Elbridge Gerry was the governor. One of the districts looked like a salamander; however, a political wit punned the district from a salamander into a “Gerrymander.”

In England, concern with “rotten boroughs” was a concern with electoral geography and the malapportionment of the size of the districts. Ultimately, the lack of equal representativeness in districts is a concern with the legitimacy of a political system. Democratic regimes are based upon the principle of the equality of the “voters” or the people who are citizens and thus have the right to make political decisions. This means that political sovereignty of the people in elections is entailed in the shape and the demographic contents of each district. When districts are drawn by legislatures or other decision-making bodies to increase the power of one group over another, the resulting legislative or other districts become inherently unjust.

In America, the courts and ultimately the Supreme Court of the United States has tolerated political gerry-

mandering, but it has ruled as unconstitutional racial gerrymandering. Cases such as *Gomillion v. Lightfoot* (364 U.S. 339) (1960) or the cases of *Shaw v. Reno* (509 U. S. 630) (1993) and *Miller v. Johnson* (515 U.S. 900) (1995), in NORTH CAROLINA and GEORGIA respectively, have dealt with the subject. The *Gomillion* case considered racial gerrymandering in Tuskegee, ALABAMA. Ordered to allow African Americans to vote and aware that whites were greatly outnumbered, the city government gerrymandered the city’s territory from a square to a contorted figure that excluded all but about seven or eight nonwhite voters. The Supreme Court in this case was dealing with electoral geography, as it was in the recent cases of *Shaw* and *Miller*, where the Department of Justice had ordered southern states to draw some districts with African American majorities. Again the court had to rule on an issue of racial gerrymandering.

There are several ways in which gerrymandered districts are drawn. In the first approach, the goal is to populate each district with a 51 percent majority for the party in power and 49 percent district vote for the minority party. Another approach is to locate as much of the minority party’s voting strength into a few “super” districts that will be carried by huge majorities approaching 99 percent. The effect is that the minority party carries a few districts but loses all the rest and thus has a much smaller legislative representation than it would have if the election districts were drawn in a way that spread the votes of the major parties in a more competitive manner. A third approach is a combination of the first two approaches. The party doing the gerrymandering can push significant numbers of minority party voters into a few districts and then spread the rest into districts where the minority party is always outvoted. This method allows the majority party to carry a large number of seats in the legislature or parliament.

Electoral geographers study votes of plebiscites. These are often votes for constitutional amendments or some form of referendum. Studies of plebiscites focus on the spatial elements associated with the vote in order to explain why people in one area voted differently from those in another area.

Electoral geographers also study the votes of deliberative assemblies such as legislatures or parliaments. The electoral geographer then seeks to move beyond the pattern of votes cast in elections or plebiscites. The focus of these types of studies is to explain blocs of votes or to determine whether the votes are in the “best interests” of the people being represented. Studies of

votes in the United Nations and other legislative bodies can verify bloc voting. The challenge for the electoral geographer is then to interpret the descriptive results in order to explain why votes were cast as they were.

Analysis of votes of deliberative bodies is risky because the motivations for voting may be hidden in a veil of diplomacy or motives in an hidden agenda. Electoral geographers then have to move beyond the description of the votes to reveal the real causes of the voting patterns.

It should be noted that elections are conducted according to rules. These rules may be used to create the illusion of fairness in an election. Or they may be used to slant the results for the benefit of one group over another. Electoral geographers can reveal these types of machinations, but at the same time, of the approximately 200 states in the world today, less than half are democratic enough for analysis of their votes by the techniques used by electoral geographers to be meaningful.

## ELECTIONS AND MAPS

Political geographers specializing in electoral geography began to study the field as early as 1916, when E. Krehheil published a paper examining British parliamentary elections. Sixteen years later, J.K. Wright published a series of maps of the presidential elections in the United States between 1876 and 1928. In addition, he presented an introductory analysis of the maps to show the influence of northern Republican Party states and southern Democratic Party states in terms of types of farming areas and ethnic minorities.

After World War II, there was a decline in interest in political geography; however, at the same time interest in electoral geography increased. A number of studies, such as those issued by V.K. Dean in 1949 on voting in Newfoundland, stimulated an interest in the subject. Other studies were produced, such as the pioneer study in electoral geography published in 1959 by J.R.V. Prescott. In his study, "The Functions and Methods of Electoral Geography," Prescott pointed out to geographers that election statistics were of value to the discipline, but just a few such studies had been done. Prescott, an Englishman, also noted that some Europeans, especially the French, and also American political scientists were engaged in the subject.

The study of electoral geography by political geographers developed new interests in the mid-20th century with the advent of the "behavioral movement." The behavioral movement developed from the research and writing of experimental psychologists like John B.

Watson and B.F. Skinner. Watson, influenced by the studies of Ivan Pavlov, rejected the study of mental operations because these could not be observed in a public manner by a scientific observer. For Watson and other behaviorists, the mind was rejected as a private matter. Instead only publicly observable data was to be admitted as matter for scientific consideration. Skinner's experiments developed into theories on conditioning. Social scientists found that these studies were useful for studying voting behavior. For political geographers, the spatially concentrated voting data became a subject of study.

Criticism of the influence of behaviorism launched the post-behavioral movement in political science and elsewhere during the Vietnam War when opponents of the war found that empiricism did not provide grounds for opposing the war. Their criticisms were basically of two types.

First, allegedly, the studies it generated were value free and products of strict empiricism. However, critics argued that the movement described but did not prescribe when it should have. Numerous empirical studies produced data, mapped results of the analysis of elections, demonstrated the geographic distribution of different kinds of laws in the United States, and ultimately seemed to document the obvious. However, empirical data is gathered on the basis of some theory. Otherwise the researcher will not have a direction for the research project or a theory of knowledge for its analysis and integration into a science as an objective body of knowledge.

Moreover, criticism of strict empiricism observed that ultimately electoral geography was a study of values. The study of inequities in election districts or the study of the distribution of votes was ultimately a study of liberal democracies (e.g., the United States) and social democracies (e.g., SWEDEN). Modern governments are prescriptive in nature because they organize power, make decisions about who should rule, and decide who gets what, when, and how on the basis of the values of their underlying theories of human nature, of justice, of liberty, and other social values.

With data from actual elections (voting data) and statistical research on voters in areas from public opinion polling and other similar studies, political geographers could ask questions pertinent to electoral geography. They would include questions such as, Is it possible to predict political responses, given certain stimuli? How are political decisions made? What leads people to vote as they do? Can any political lessons be learned from this?

After 1960 studies in electoral geography grew more rapidly as attention was paid to spatial patterns of voting behavior in an attempt to determine underlying factors influencing voters. Other studies developed a variety of quantitative techniques for analyzing voting results. These techniques included multiple regression analysis in combination with maps, factor analysis, and correlation techniques.

### NEW ELECTORAL GEOGRAPHERS

In 1969, D.R. Reynolds and J.C. Archer tested patterns of party support in the 1967 mayoral election in Indianapolis, Indiana. They represented a new breed of electoral geographers seeking to test for spatial processes such as contagion and contextual influences. They used a complicated mathematical analysis of the vote to test for correspondence with a normal distribution. They then examined the distribution for its spatially significant deviations from randomness. They then analyzed the distribution for explanatory components and then tested them for normality and contiguity. They then applied further mathematical analysis to show that variations in the vote were explained in terms such as socioeconomic class and race.

In 1970, T.G. Glanville published his study of “spatial biases” in the votes after a federal election in the Australian state of Victoria. His study revealed two types of spatial biases. Both of the spatial biases were patterns of gerrymandering that caused the opposition to “waste” their votes.

Another aspect of electoral geography is the role of money. Elections determine who gets to control governmental spending. Studies in the late 1970s by R.J. Johnston documented how political parties in Great Britain and the United States used money to encourage political support. In his study of British elections, he documented the success of the Labour Party in the bi-elections of 1977. The success was preceded by raising the status of the marginally loyal district of Grimsby to Development Area status. The change meant more financial aid from the government for the area and seems to have been translated into votes. Johnston also studied the use of “pork barrel projects” to curry favor with voters in some districts. The term *pork barrel project* is a synonym in American politics for unnecessary and wasteful government spending for political purposes. The image is of a wooden barrel filled with salt pork (fat back) being distributed to slaves at special events in early American history. The projects that Johnston studied were distributed money by politicians who were on Congressional committees exercising

oversight of the National Aeronautics and Space Administration, the Atomic Energy Commission and the Defense Department.

Since the 1980s studies of American presidential elections have used factor analysis to research and examine multiple elections at one time. Two types of factor analysis have been used: the T-mode and the S-mode. The T-mode factor analysis combines elections over several periods of time. The analysis then shows similarities and differences between elections decades apart.

The S-mode type of factor analysis groups areas under study into regions to show similarities in areas. The United States has historically experienced sectional conflict between the southern, the northern and the western states. The S-mode type of factor analysis mathematically demonstrated the long-term influence of sectionalism in presidential elections.

Electoral geography has come to play a significant role in American presidential elections. The president of the United States (and the vice president) are elected by electors to an electoral college. The electors vote for the president and vice president in their respective state capitals. The electors to the electoral college in all but two states vote in a bloc. They vote this way because the vote must be cast according to election laws passed by the dominant party in each of the 50 American states. The two major parties in the United States are the Democrats and the Republicans. The electoral results after an election shown on electoral maps used by the television networks have in recent times been colored red for Republican and blue for Democrats.

### RED AND BLUE STATES

After the 2000 presidential election in the United States, pundits began talking about the “red” (Republican) and “blue” (Democratic) states. These terms grew in popularity and were used by the news media to simplify speculations on the vote in the run-up to the election. There were maps easily available through the internet and in newspapers showing the vote for president. The important map was the one depicting the placement of the electoral votes in the states. These became the red and blue states.

However, maps were also easily available that showed the vote for George W. Bush (Republican) and John Kerry (Democrat) by county. There are just a little over 3,000 local units of government in the United States called counties.

In LOUISIANA, the local units are called parishes and are modeled after a French form of government, and in

While the popular vote was somewhat close, with only 3 million more votes for Bush than Kerry, the geographic distribution was revealing. Maps colored red and blue to show the vote by county showed that Bush had carried 83 percent of the counties in the United States. It also revealed that Kerry's vote was concentrated in large urban areas with heavy African American populations and in some rural counties in the southern states that have majority black populations. It also showed that Kerry carried several Native American reservations and groups of Hispanic voters, such as those on the lower Rio Grande in TEXAS.

These and other maps were quick used by pundits to explain the vote in the red and blue states in terms of ethnic, cultural, economic, educational factors, and other cultural features such as religious participation. Revealing also was the evidence that many areas voted in a manner that seemed to be opposed to their economic interests. The conclusion quickly drawn by pundits was that these were social conscience votes in support of social policies of the Republicans or the Democrats, or they were votes in support of or in opposition to the war in Iraq. The ongoing politics in America is now clearly utilizing electoral geography to make political arguments.

It is likely that attacks on the electoral college system of voting in the United States will be presented in

future decades in terms of electoral geography. The claim that voting by anything other than direct popular election is unfair is frequently urged by political opponents of the electoral college system. It causes the voters of one party in states dominated by another party to “waste” his or her ballot.

This argument is unlikely to be effective because the electoral college, like the representation in the Senate of the U.S. Congress, is weighted in favor of the “small” states. These are usually the least populated states and also those with fewer economic resources. However, the Constitution of the United States was rigged this way in the beginning to give to the small states more power than they would have had otherwise. It means that candidates are encouraged to visit most if not all states in their hunt for votes. A system of direct popular election would eliminate the need to visit most of the areas of the country. Candidates would then concentrate their campaigns on the voters in the large population areas.

Almost immediately after the 2004 presidential election in the United States there was a non-violent revolution in UKRAINE. Voting irregularities, denounced by both Ukrainians and foreign observers, eventually forced a new election that was won by the Ukrainian nationalist candidate and former Prime Minister Viktor Yushchenko. An electoral map of the first and second votes revealed the issues. The Dnieper River was the boundary between majorities of Russian speakers and Ukrainian speakers. The split was between those who wanted to return to RUSSIA and those who wanted to tie Ukraine’s future to the NORTH ATLANTIC TREATY ORGANIZATION and the EUROPEAN UNION.

Electoral geography has, through the internet, moved into the mainstream of American politics. It is now commonplace for newspapers to print maps of districts and to provide stories about electoral geography. Electoral geography is also affecting political perceptions in other parts of the world. The future for electoral geography is wide open as liberal democracy or social democracy is adopted by former totalitarian or traditionalist regimes.

## elevation

ELEVATION CAN BE defined as a measure of the height above mean sea level. When specifying a location on (or above) the surface of the Earth, elevation is commonly considered to be the third coordinate, complementing measures of LATITUDE AND LONGITUDE. Similarly, bathymetric measurements provide a depth below mean sea level to the floor of a body of water. Mean sea level is defined as the still water level averaged over time so that periodic changes in sea level—such as those caused by the gravitational effects of the moon and sun—are averaged out.

The choice of mean sea level as the baseline (or datum) for elevation is an arbitrary, though reasonable, option. Based on the behavior of water, early practitioners of geodesy (the study of the shape of the Earth) believed that the oceans of the world were balanced by the Earth’s gravitational pull, forming a perfect sphere with the exception of the transitory distortions caused by waves and the periodic changes due to the tides.

This decision is arbitrary since elevation could have been defined as a measure of distance from the center of the Earth or a measure of distance below the highest known point on the Earth, among other possible choices. Since there is no natural zero level for eleva-

tion, collections of elevation data should be considered to be of an interval type.

Unfortunately, mean sea level is not constant at all places. There are irregularities in mean sea level because of varying concentrations of mass in different parts of the Earth, and the resultant variations in gravitational pull. Additionally, the effects of currents and differences in water temperature and atmospheric temperature and pressure create variances in mean sea level. Moreover, mean sea level is historically measured with a tide gauge, which is an instrument that uses land-based benchmarks to record the sea level. A change in mean sea level can therefore result from a change in the actual sea level or a change in the height of the land that supports the tide gauge. Given all these distorting factors, mean sea level must be considered as the zero elevation (also termed the vertical datum) for only a local area. When mean sea level has been determined for a local area, this datum is used to compute elevations in surrounding areas with surveying tools and the techniques of leveling and triangulation.

Elevation can be represented graphically in several different ways. The U.S. Geological Survey (USGS) has historically produced several map series that contain elevation data both in the form of points where known elevations have been surveyed and in the form of contour lines that produce an approximate elevation surface. Contour lines connect locations on the Earth's surface that have the same elevation value. Generally speaking, elevation contour maps use a constant contour interval (for example, 10 ft) so that the separation between contour lines represents a consistent change in elevation. This results in contour lines that are close together in areas with steep terrain, and further apart in areas with less dramatic elevation changes. The contour interval may not be constant for all maps in a map series, since the best contour interval for a given map is a function of the variation in elevation across the map and should be chosen in such a way that sufficient elevation detail can be visualized.

Although printed contour maps continue to prove useful for many applications, elevation data are increasingly processed digitally. There are several common digital formats, also known as digital elevation models (DEMs). One such DEM is termed a triangulated irregular network (TIN). A TIN begins with a set of points where the elevation has been calculated. These points can occur at any location but ought to occur at points where there is a major change in the shape of the elevation surface, such as at mountain peaks, valley floors, or the edge of cliffs. The denser the

number of elevation points, the greater the detail captured by the TIN. In order to generate the elevation surface, a set of nonoverlapping triangles are created by connecting neighboring points.

Each triangle represents a planar elevation surface, and the slope and aspect (the orientation angle of the slope with respect to north) are constant for each triangle. TINs are a very efficient method for storing elevation data, in part because they allow for variation in the density of elevation points based on variability in the elevations being mapped.

A more widely used method for digitally representing elevation data is the raster (or grid) method. A raster DEM divides a portion of the Earth's surface into regularly spaced (and usually rectangular) grid cells, arranged into rows and columns. Each cell contains a single elevation value. Based on the cell values and the values in neighboring cells, the slope and aspect can be calculated for the elevation surface. The raster method allows for easier manipulation of elevation data than the TIN method, although it requires greater amounts of computer disk space to store the large number of regularly spaced elevation values. Rasters are always regularly spaced, so there is no way to vary the density of elevation observations within a single raster to account for greater or lesser variability in relief. High-quality DEMs in raster format are available at several different cell resolutions.

## enclave

AN ENCLAVE is a political unit that is completely enclosed within a foreign territory. It is called an "exclave" from the perspective of the country that has sovereignty over it. An enclave can also exist on a subnational level when a subdivision has land outside its parent territory. The enclaves can be created for geological, historical, or political reasons. *Enclave* is a French word of the diplomatic language, which passed into the other languages; it comes from the Latin *in-clavatus*, meaning "closed with the key."

Some enclaves are small nations completely surrounded by another one, for example SAN MARINO and VATICAN CITY, exclaves of ITALY, and LESOTHO, exclave of SOUTH AFRICA. Some nations can be enclaved except for a small part of the coast, as in the cases of GAMBIA, BRUNEI, and MONACO. Some other territories cannot be reached from their nation except by international waters, or are enclosed in other countries except for a small coast fragment: This is the case of the Spanish towns of Ceuta and Melilla in the north of MOROCCO and of the British colony of GIBRALTAR in the south of SPAIN. True enclaves are the Belgian municipality of Barle-Nassau in the NETHERLANDS; Busingen in GERMANY (exclave of SWITZERLAND); Campione d'Italia in Switzerland (exclave of Italy); and the town of Llívia in Spain (exclave of FRANCE). Madha is a land of OMAN enclaved in the UNITED ARAB EMIRATES; INDIA has 106 exclaves in BANGLADESH and Bangladesh has 92 exclaves in India.

A lot of enclaves in history do not exist anymore. Until 1861, the Pontifical State had the exclave of Benvento in south Italy, and the Papal States also had the exclave of the Comtat Venaissin, the region around the city of Avignon, enclaved in France, from 1274 until 1791. HONG KONG, until 1997 administered by Great Britain, now is part of CHINA. There are territories that are not true enclaves, but are practically. Some practical enclaves are not geographically detached from their nation, but are more easily reached by entering another country because of their location. Some villages of ESTONIA, for example, can be reached only by a road passing inside Russian land.

The more frequent type is the subnational enclave. Administrative division of countries, often for historical reasons, can create small lands enclaved in another province, region, or municipality. In AUSTRALIA, the Australian Capital Territory is an enclave of New South Wales. In AUSTRIA, Vienna is an enclave of Lower Austria. In COLOMBIA, Bogotá is an enclave of Cundinamarca.

Other examples include: In Belgium, the Brussels-Capital Region is an enclave of Flanders, and also the capital of Flanders. In Italy, a lot of municipalities have exclaves: Città di Castello, in the region Umbria, has the exclave of Mount Ruperto enclaved in the territory of the Marche region.

Ethnic enclaves are communities of an ethnic group inside an area where other ethnic groups are the majority. The historic Jewish ghettos in Europe and the Native Americans reservations in the UNITED STATES are some examples.

## energy geography

ENERGY GEOGRAPHY IS a subdiscipline of geography that draws from many philosophical and thematic traditions, but it is primarily positioned in the interface of environmental and economic concerns. The extraction, harnessing, and consumption of the natural resources that supply society with our energy needs have always been central to economic activities. Over time, however, it has also become apparent that we face scarcity of resources and negative consequences of pollution, and the environmental component of energy analysis has grown stronger. As such, the focus on energy in geography is important because it addresses one of the central aspects of the discipline—the human-environment interaction.

Energy can be defined as the capacity for, or equivalent of, doing work. Society needs energy for transportation, heating and cooling of buildings, powering production processes in industry, and various household needs. Sources of energy are classified as renewable or nonrenewable. Nonrenewable is primarily fossil fuels: oil, coal, and natural gas. More than 80 percent of U.S. energy needs are satisfied by fossil fuel. Renewable energy sources include hydro-electric, solar, and wind power. Nuclear power occupies a special position not commonly classified as either renewable or non-renewable. Often, the energy source itself has to be converted to a usable form. The most common and versatile form is electricity, which is generated in coal-fired power plants, nuclear plants, or hydroelectric dams. In the transportation sector, gasoline and other oil derivatives directly power the combustion engine. Another example of this direct use is when natural gas is utilized for home heating.

Energy geography may not be as well defined as economic or cultural geography. For example, courses in energy geography are infrequent in geography departments around the country, although energy issues

Energy geography is about the distribution and consumption of fuel resources around the world. (Source: British Petroleum)

are often addressed in other forums. Geographers' interest in energy has mirrored the developments in society at large. With the advent of the environmental movement in the 1960s and 1970s, and the subsequent oil crisis and surging energy costs, energy studies became increasingly popular in the 1970s in geography as well as in the research community in general. After the immediate crisis, energy concerns were not prioritized, but socioeconomic and technical solutions continue to make our energy system more efficient. There is still much work to be done, however, and in this endeavor, geographers can be found not only in academic departments but also in government agencies and laboratories and in private industry.

What, then, is the geographic perspective on energy? Inevitably, society's energy use has spatial dimensions and impacts. Here is a selected list of themes of concern to energy geographers:

First, energy geography is about the distribution of resources over space. The global location of natural resources such as oil, gas, and coal sets the parameters for our energy needs. The location of fossil fuel is determined by geology, but the potential for renewable energies also exhibits spatial variation because of geomorphic (hydroelectric) and climate (solar and wind) factors.

The extraction of energy-generating resources and their strong concentration in some areas has led to regional economies being heavily dependent upon energy industries. Such dependency can lead to large profits, but also fluctuations in income as raw material prices are volatile on the world market. Resource extraction

may not produce diverse and stable long-term regional economies. Access to strategic energy resources, particularly oil, can also have geopolitical ramifications.

The harnessing of energy for human purposes has environmental and social impacts on the supply side. Hydroelectric power, although emission-free, has land-use impacts as dams inundate large areas and irreversibly alter river hydrology, riparian vegetation, and habitats. Moreover, the people reaping the benefits of hydroelectric power are not necessarily the same (or located in the same place) as those who are impacted negatively (those displaced). Wind power is facing related problems on a smaller scale; in this case, wind generators detract from the scenic aspects of the landscape. In addition, coal mining creates the problems of acid mine drainage and strip mining, while oil drilling can create leakage and contamination of the local environment.

The geographic difference between resource location and energy demand necessitates transportation and distribution. The transportation of oil on ocean-going vessels has frequently led to devastating oil spills. Distribution systems like pipelines also trigger environmental concerns, and like power lines, the construction of such networks is often opposed by residents and localities in their proximity.

Then there are environmental and social impacts on the demand side. The effects of the energy conversion or consumption process result in emissions, particularly gaseous air emissions. Pollutants include various forms of sulfur, nitrogen, and carbon oxides with environmental effects such as smog, acid rain, and global warming. Adverse human health effects (respiratory problems and cancer, for example) may also ensue.

Nuclear energy production, on the other hand, creates a particularly severe waste issue. Finding a solution to radioactive waste storage is a locational problem that spans geography and politics.

Such environmental problems are not inevitable or unavoidable. Geographers have therefore been interested in the spatial organization of energy systems. The UNITED STATES, for example, has the highest per capita energy consumption in the world. This high consumption level is, in part, a result of the sprawling nature of settlement patterns. To achieve a more sustainable society, it has to be spatially organized so as to enable recycling, minimize energy consumption, and utilize renewables, while at the same time allowing for a reasonable level of economic growth. One problem is that the environmental consequences of our actions are often "hidden" as we as individuals are not immedi-

ately impacted. Concepts developed to illuminate such relationships include the ecological footprint idea and life-cycle analysis. We must also take into account human behavior and our consumption choices when it comes to energy use.

Geographers can contribute to efficient and equitable energy systems by critiquing and suggesting energy policy. This includes conservation efforts and highlighting social consequences of policy making. We are currently dependent on fossil fuels and the infrastructure built to support it, but a transition to other energy sources, including perhaps hydrogen- and biomass-based fuel technologies, will inevitably occur during the 21st century.

## entrepot

AN ENTREPOT (from the Latin *emporium*) is a settlement founded specifically for commercial activity or a market or mart located within or on the periphery of an administrative/political center. The origins of the entrepot are traced to the commercial behavior of ancient societies.

Traders entering foreign territory were exposed to numerous natural and cultural hazards. In addition to facing harsh traveling conditions, they might be attacked by brigands or find themselves in places where they did not know the local languages or customs and were subject to territory-specific laws under which they would find no protection. Foreign merchants required neutral sites of exchange, which would offer provisions, lodging, interpreters, and legal and economic

safeguards. Designated, controlled trading stations met the needs of the host society as well. Restricting stranger merchants to an entrepot protected the local population from potentially threatening foreign influences. Moreover, elites could use control over the flow of prestige commodities, such as items of precious metal, to maintain their social position, redistributing the imported goods locally through processes of gift exchange.

Entrepots for foreign exchange were generally located at the boundaries dividing political territories or distinct economic or environmental zones, such as the SAHEL of Sub-Saharan Africa, which lay between the desert and the savannah. Situated along TRADE ROUTES, the entrepot had to be accessible to foreign merchants—for example, a place with a functional harbor—which in turn was connected to inland distribution networks. Because the entrepot also provided lodging and provisions to visiting traders, who might spend long periods there before returning home, nearby supplies of potable water and an agricultural HINTERLAND also were important.

The population and administrative organization of the entrepot varied with its function and complexity. Whether a seasonal market or year-round point of exchange, a site required a permanent population to maintain it. The permanent service population would consist either of locals or of permanent representatives of a foreign trading diaspora, who would learn the territory's language, look after the foreign community's temples, and cultivate relations with the host society.

If the entrepot had an ethnically and linguistically mixed population, it would be divided into distinct residential neighborhoods. Craftsmen resided at the entrepot as well, producing not only goods for exchange but also producing and repairing gear needed by the traders—everything from combs and shoes to ships and carts. Finally, port officials collected tolls and adjudicated disputes.

Extensive entrepot networks arose with the intensification of long-distance trade throughout the Mediterranean and Near East in the first millennium B.C.E. The network in classical Greece (5th to 4th centuries B.C.E.) consisted of two types of entrepot (Greek *emporion*): harbors attached to but separated from a polis (city) by walls (for example, Athens's harbor, the Piraeus); and permanent Greek commercial colonies located on the periphery of the Greek world (for example, Naukratis in Egypt). The first type funneled commodities in and out of Greek cities. The second acted as an interface between the Greek world and non-Greeks, giving the

Greeks access to metals and other raw materials that were not available in the Greek home territories.

The Romans developed extensive networks of entrepôts, linking their resource bases in northwestern Europe, northern Africa, and the Near East with INDIA's Malabar Coast, and the SILK ROAD, extending across Central Asia to CHINA via a system of desert emporia (caravanserais). Following the collapse of Roman control in northwestern Europe, the Frankish and Anglo-Saxon kingdoms established their own emporia trading networks along the coasts of the North and Baltic seas in the 7th and 8th centuries (for example, LONDON, Dorestad, Cologne), which quickly spread to Scandinavia and RUSSIA.

This period also witnessed the formation by the Islamic caliphates of entrepot networks along the coasts of the INDIAN OCEAN, which acted as interface points with non-Islamic peoples for the acquisition of slaves, spices, and other luxury items from Africa, INDONESIA, and China. In the first half of the 16th century, however, Portuguese and, later, English and Dutch trading corporations assumed control of the Indian Ocean and Southeast Asian entrepôts. Here, the host communities eventually lost control of the trade and actions of the foreign merchants, with European traders coming to control not only the entrepôts but the adjoining hinterlands and their resources as well.

The integration of the global economy during the last two centuries has transformed the character, but not the function, of the entrepot. International trade now takes place in multifunctional centers, such as the financial and administrative metropolises of NEW YORK CITY and London. Entrepot is now used to describe distribution points within cities, such as warehouses.

## epidemiology

THE WORD *EPIDEMIOLOGY* is derived from the Greek *epi* ("upon"), *demos* ("people"), and *logos* ("study

of"). It refers to the study of phenomena that have been put "upon" people, specifically, afflictions that weigh upon the health of a population over space and time. Epidemiology is a multidimensional science that deals with the study and occurrence of diseases, attempting to answer many questions: the origin, causes, loci, and spatial distribution of diseases and how these aspects have changed over time. To answer these questions, epidemiology often takes a historical perspective and borrows from the fields of medicine, ecology, anthropology, sociology, and demography. Geography is involved because the spread and spatial patterns of diseases are analyzed.

Epidemiology in the Western world can be traced back to the ancient Greek civilization, where Hippocrates (460–388 B.C.E.) laid the foundations for modern epidemiology through observation and description of diseases in relation to the environment. Sporadic references to epidemiology occur throughout history, such as references to links between illnesses and environment, and between public health and sanitation. Scientific inquiry gained ground by the 17th century, and like other sciences, epidemiology has shifted its theoretical allegiance many times since.

Early epidemiological studies were descriptive in nature, detailing disease symptoms, areas of influence and affected population groups and subgroups. Causes were often speculated upon based on the reigning belief structure. In the 18th century, cause was often based on the miasma theory (diseases borne by air). The 19th century saw the popularity of the germ theory, which focused on the role of microorganisms in causing and spreading disease. Currently, epidemiologists believe that a number of factors (for example, environment, microorganisms, genetics) play into creating diverse disease patterns.

John Snow, a 19th-century London physician, performed one of the first formal epidemiological studies in modern history, which has since become a legend. London had been ravaged by cholera, but the cause was yet unknown. As for all contagion in the day, miasmas were believed to be the culprit, but Snow suggested that the disease spread through contamination of food and water by way of the water supply. He was finally able to validate his theory during London's 1854 epidemic by mapping the locations of cholera deaths and of water pumps in the city. He found that the Broad Street Pump showed the greatest concentration of deaths near it. He suggested the removal of its handle, which, incredulously for the townspeople at the time, resulted in a containment of the epidemic.

This exercise demonstrated the importance of sanitation and prevention measures in the containment of diseases and epidemics, a lesson used even today.

It would be erroneous to believe that epidemiology is a Western science. “Non-Western” or traditional civilizations present evidence of epidemiological studies that predate even the work of the ancient Greeks. Careful observation of symptoms and possible causes had been noted in the civilizations of EGYPT, CHINA, INDIA, and the Americas. Treatises such as *Charaka Samhita* by the Indian physician Charaka, and Zhubing Yuan Hou Lun (*On Pathogenesis and Manifestations of All Diseases*) by the Chinese physician Chao Yuanfang were written, which contributed greatly to the development of epidemiological studies and the promotion of public health. Sadly, much of this was lost, downplayed, or overshadowed by Western knowledge and paradigms.

Some of the benefits derived from epidemiology are a better understanding of the causes and etiology behind illnesses and health problems; the impact of changing technologies, environments, and lifestyles on our health; the ability to project longevity and morbidity patterns on the basis of this understanding; the ability to provide prognoses and generalizations; and finally, the provision of solutions through prevention and public health measures.

These uses are evident in the case of AIDS (acquired immunodeficiency syndrome), which was first identified only in isolated cases in the early 1970s but has now become a pandemic (global epidemic). Through epidemiological studies, it is now known that AIDS is primarily caused by the human immunodeficiency virus (HIV). Two strains of this virus exist, one originating in Central Africa and the other in West Africa. Both have diffused over travel routes to other parts of the world.

Epidemiology has revealed the nature, origin, diffusion routes, and modes of transmission (blood and blood product transfusions, sexual contact, needle sharing, and mother-to-child) of AIDS. Early identification of symptoms and risk factors, more accurate prognosis, and identification of geographic patterns of occurrence are instrumental in containing its rapid spread and in formulating effective health programs.

The descriptive style of traditional epidemiology has been replaced by a more complex set of theories and methods comprising the current modern approach, which uses statistical techniques and models. However, epidemiology’s status as a true science is often questioned on the grounds that it lacks a theoretical matrix.

However, epidemiology does claim underpinnings such as the “agent-host-environment” triad and “iceberg” concept. “Iceberg” is an analogy that describes a widely occurring phenomenon in healthcare, that of undiagnosed or misdiagnosed cases being hidden from view, much like the unseen portion of an iceberg. These theories are subject to the rigors of testability through the use of appropriate measures and tools. Some commonly used methods and tools are cohorts, case-control studies, and rates and ratios.

As epidemiology advanced, it became apparent that diseases were affected by geography, in terms of both absolute location and what was contained within that location. This realization of areal variation of diseases contributed to the legitimization of medical geography as a field of study in its own right.

Two approaches evolved: disease ecology and disease diffusion. Disease ecology deals with the interplay among environmental conditions (physical and social), the human host, and the agent of the disease. Disease diffusion examines the spread of diseases from their points of origin. An integrated approach is probably the best means to a complete “picture of health.”

## Equatorial Guinea

**Map Page** 1115 **Area** 10,831 square mi (28,051 square km) **Population** 510,473 **Capital** Malabo **Highest Point** 9,870 ft (3,008 m) **Lowest Point** 0 m **GDP per capita** \$4,900 **Primary Natural Resources** petroleum, wood uranium, gold, manganese.

EQUATORIAL GUINEA is located in west-central Africa just north of the equator. It is made up of Rio Muni on the African mainland and the islands of Bioko, Annobon, Corisco, Elobey Grande, and Elobey Chico. Rio Muni is bordered by CAMEROON to the north and by GABON to the east and south. The Campo River forms part of the northern boundary with Cameroon, and the Rio Muni River forms part of the southern boundary with Gabon. These two rivers, along with the Mbini River, located in the center of Rio Muni, are the three largest rivers in the country.

Rio Muni contains 93 percent of Equatorial Guinea's total landmass, and 80 percent of the population lives here. The major urban areas in Equatorial Guinea include Malabo and Luba on Bioko Island and Bata, Mbini, Ebebiyin, Mongomo, and Evinayong on the mainland of Rio Muni. Both Bioko and Annobon islands are volcanic. Equatorial Guinea has a tropical climate that is hot and humid year-round. Along the coastal plain, the city of Bata is cooler and drier than the rest of the country. Rio Muni is mainly hilly terrain averaging about 2,000 ft (610 m) in elevation with some 4,000-ft (1,220-m) peaks.

Bioko Island, which was called Fernando Po until the 1970s, lies about 25 mi (40 km) from Cameroon and is the largest island in the Gulf of Guinea, covering 780 square mi (2,017 square km). It was discovered in 1471 by Portuguese explorer Fernando Póo, who was seeking a route to INDIA. PORTUGAL controlled the island until 1778, when it ceded this, surrounding islets, and commercial rights to the mainland between NIGER and the Ogoe River to SPAIN in the Treaty of Pardo in exchange for territory in South America (mainly territories in BRAZIL). Bioko is made up of three extinct volcanoes, the largest of which, Pico Basile, reaches up 9,870 ft (3,008 m). The coastline is 120 mi (195 km) long, very steep to the south from the volcanoes rising up, and much lower in the northwest, with good harbors at both Malabo and Luba.

Also along the northwestern coast between Malabo and Luba are several scenic beaches. Indigenous to Bioko Island are the Bubi people constituting 15 percent of the population. The Bubi are descendants of slaves liberated from western Africa by the British during the 19th century.

Originally, it is believed that the first inhabitants of Equatorial Guinea were Pygmies who still live in isolated areas of northern Rio Muni. The majority of the people of Equatorial Guinea are of Bantu origin, most of these being from the Fang tribe, which makes up 80 percent of the total population of Equatorial Guinea.

Spain granted Equatorial Guinea independence on October 12, 1968. After gaining independence, they suffered for 11 years under a repressive dictatorship that suppressed the local economy. Equatorial Guinea's economy was mainly based on developing the rich volcanic soil for agricultural use. They grow cocoa, coffee, plantains, cassavas, sweet potatoes, and palm oil. They are slowly developing their fishing industry with the help of Spain, NIGERIA, and MOROCCO. Oil and gas discovered offshore is now the main export and will continue to drive the economy for years to come.

## erg

THE TERM *erg* is the Bedouin name for a very large body of sand dominated by sand dunes. Bedouins are an African tribe of nomadic herders living in the northern SAHARA DESERT. Two equivalent English-language terms are *sand sea* and *dune field*. Transverse dunes typically are part of ergs, or sand seas. As sand is seemingly everywhere, the dunes appear as waves in a sea of sand. Hollywood made this sandy landscape famous in classic movies such as *Lawrence of Arabia*, in which sword-wielding Arab horsemen galloped across seemingly endless seas of velvet-soft dunes. Contrary to popular belief, ergs are usually not continuous deposits of fully formed dunes; small inter-dune exposures of underlying bedrock, soil cover, or deposits of ephemeral lakes and streams are common.

Ergs require huge supplies of sand. The sand of an erg is usually from nearby dry lakebeds, ALLUVIAL FANS, smaller dune fields, remnants of earlier sand seas, or coastal dunes. The Namib erg, which stretches along the southern coast of Africa, receives its sand from nearby coastal dunes. Some ergs are surprisingly far from their sand supplies. This fact is especially true in the Sahara Desert of northern Africa, where sand may flow thousands of kilometers before entering a sand

sea. Wind patterns will also affect sand supply. For instance, dunes in southern Africa and AUSTRALIA tend to be linear and form whorls (or wheelrounds) that stretch outward from their central areas. These whorls indicate an counterclockwise movement of sand in response to continental anticyclones that dominate the two regions. Topography also affects sand supply. For instance, several ALGERIA sand seas occur close to upland areas, where the uplands extend across the regional trend of sand drift. Some of the more striking sand seas occupy topographic basins. The Simpson in Australia and the Taklimakan in CHINA are examples.

Ergs or sand seas are impressive for their areal coverage. There are major ergs in northern Africa, southern Africa, the Arabian Peninsula, Central Asia, PAKISTAN, and China. The largest contiguous erg covers 1 million square mi (2.5 million square km) in southern Africa's KALAHARI DESERT. Natural vegetation has stabilized most of this sand sea. The largest active sand sea is RUB AL KHALI in SAUDI ARABIA, which stretches across 220,000 square mi (560,000 square km). The region with the greatest number of ergs is northern Africa's Sahara Desert; it has 27.

The proportion of the world's deserts covered in sand varies greatly. AUSTRALIA's large desert is the sandiest, more than 50 percent of it under sand. North American deserts' 2-percent coverage makes that continent's deserts the least sandy. North America has no ergs as a result. The continent's largest dune fields—the Algodones in CALIFORNIA, White Sands in NEW MEXICO, and Great Sand Dunes in COLORADO—are too small to qualify as ergs.

## Erie, Lake

LAKE ERIE, bordered by the province of Ontario in CANADA to the north, NEW YORK to the east, PENNSYLVANIA and OHIO to the south, and MICHIGAN to the west, is the shallowest of the Great Lakes at only 62 ft (18.9 m) and it remains the smallest in volume. Lake Erie is 241

*After decades of pollution, Lake Erie's ecosystem has returned to a more stable state with some fish reappearing in its waters.*

mi wide (380 km), and 57 mi (91 km) from north to south and has 871 mi (1,401 km) of shoreline. Because of its shallowness, Lake Erie is the warmest of the Great Lakes in the summer, meaning it is the most biologically productive, and during the winter, it is the only lake out of the Great Lakes to freeze. Lake Erie is one of the five large freshwater lakes in North America. The other lakes surrounding Lake Erie are Lake SUPERIOR, Lake MICHIGAN, Lake HURON, and Lake ONTARIO. Eighty percent of the lake's water flows in through the Detroit River, carrying water from lakes Superior, Huron, and Michigan. Lake Erie is the most heavily populated freshwater BASIN in the world. There are 17 metropolitan areas within the basin.

Ecological problems have threatened this site more so than any other of the Great Lakes. Historically, this lake was used moderately by Native Americans for food and water. Later, when the Europeans arrived, they found a somewhat stable ecosystem that remained

so mainly because of the Europeans' interest in animal furs. However, that all changed when the large influx of immigrants arrived and began to utilize the land for agriculture and the water for fisheries. Industrialization and urbanization soon followed slowly lowering the quality of the water. Some of the many prominent problems was bacterial contamination, putrescence, and floating debris in the water. This undoubtedly led to diseases such as typhoid fever being contracted by people exposed to the water.

In the 1950s, Lake Erie also was the first of the Great Lakes to display lake-wide eutrophic imbalance. Eutrophic imbalance refers to the imbalance of minerals and nutrients that promote proliferation of plant life in lakes and ponds. This was present because of the high levels of phosphorus output by factories in the very highly populated Lake Erie basin, and it had dire consequences on the lake's ecosystem. Depleted oxygen levels were found along with excessive algal growth and the disappearance of entire families of fish.

The 1960s brought growing public concern regarding the state of the lake's water. Lake Erie was actually called the dead lake by the press. It evolved from a stable ecosystem to one very much affected by artificial fertilizers used by the surrounding farmers, waste from the surrounding communities, and factory waste. Floating waste, putrescence, and bacterial contamination were all of great concern to both the U.S. and Canadian governments.

This concern brought much needed government measures to stabilize the lake's ecosystem. Greater investment in pollution research by the U.S. and Canadian governments and efforts to regulate the toxicity and level of waste being released by the factories began in earnest.

In 1987, the United States and Canadian governments signed the Great Lakes Water Quality Agreement (GLWQA) to develop a management plan for the Great Lakes. More specifically, under the GLWQA, they created the Lake Erie Lake-Wide Management Plan (LaMP), which included efforts from local, municipal, state and federal offices in the four surrounding states of Michigan, Pennsylvania, New York, and Ohio and the province of Ontario. The four subcommittees within the LaMP are; Beneficial Use Impairments, Sources and Loadings, Ecosystem Objectives, and Public Involvement.

Thanks to the efforts made by both the American and Canadian governments, Lake Erie's ecosystem has returned to a more stable state with lower phosphorus output levels, and it appears as if the eutrophic imbalance

is being adequately dealt with by the governments as some species of fish have returned to the lake.

## Eritrea

**Map Page** 1114 **Area** 46,662 square mi (121,320 square km) **Population** 4,362,254 **Capital** Asmara **Highest Point** 9,959 ft (3,018 m) **Lowest Point** -248 ft (-75 m) **GDP per capita** \$700 **Primary Natural Resources** precious metals, natural gas.

ERITREA IS LOCATED in northeastern Africa, an area known as the HORN OF AFRICA, where the RED SEA empties into the INDIAN OCEAN. Eritrea is bordered to the south by ETHIOPIA, which until 1993 incorporated Eritrea within an autonomous zone, to the west by SUDAN, and to the southeast by DJIBOUTI. Among these neighbors, Eritrea shares much geography and climate, particularly with Ethiopia.

In particular, the Red Sea and Indian Ocean determine much of the country's weather. Likewise, a large central highland plateau extends northward from Ethiopia and helps to moderate Eritrea's temperatures. These highlands are generally wetter and cooler than the coastal lowlands to the east or the plains to the southwest. The country's major population settlements are concentrated in these temperate highlands. Eritrea has two rainy seasons, with the first and heavier occurring during the summer and the lighter one in the spring.

Eritrea was dominated by other larger powers, falling under the sway of first the Egyptians, Ethiopians, and finally the Italians. In 1869, imperialists purchased the southern port of Assab and quickly expanded their holdings with further purchases northward to Massawa. Italian colonialists confronted the Ethiopians, which after 1889 led to the Italians ex-

panding into northwestern Ethiopia. Subsequently, the Italians launched an invasion of Ethiopia from their colony Eritrea but were decisively defeated at the Battle of Adowa in 1896. This defeat led the Italians to concentrate on developing Eritrea for its economic and strategic importance. In 1935, the Italians attacked and conquered Ethiopia, merging the two colonies until the British defeated the Italians in 1941. At the end of the war, the United Nations assigned Eritrea to Ethiopia, making Eritrea an autonomous region within Ethiopia in 1952. Relations frayed as the Eritreans demanded their independence. The Ethiopians dissolved the autonomous zone and annexed Eritrea in 1962, sparking 30 years of Eritrean armed struggle.

In the late 1970s and through the 1980s, the situation dramatically improved for Eritrea. First, domestic opposition groups in Ethiopia launched an insurgency against the Ethiopian regime. Second, the Eritrean People's Liberation Front made significant headway on the battlefield, driving the Ethiopian military from most of Eritrea by 1988. Shortly thereafter, the Soviet Union ceased its military aid to the regime, denying the military equipment necessary to pacify Eritrea and fight the Ethiopian insurgents. In 1991 the regime crumbled, ending the hostilities and granting Eritrea its independence. Tensions remained, however, and in 1998 the two states clashed again in a brutal border dispute that ended with a peace treaty in 2000.

## erosion

**EROSION HAS MADE** huge changes in the surface of the Earth and is still doing so today. Erosion is the removal of materials from the Earth's surface by a variety of processes. The material is eventually deposited elsewhere, often far from where it started. Most erosion is caused by the action of wind, water, or ice. Water causes the most erosion. Weathering is the breaking down of rock into smaller particles. Erosion differs from weathering in that erosion involves something moving—wind, rain, or a glacier.

During the natural process of erosion, the landscape is changed over thousands or millions of years. Mountains are worn down, valleys are filled in, and rivers change their courses. These changes are gradual, but many of the practices of man speed up the process of erosion and cause serious problems around the world. Construction is one of the biggest culprits. Topsoil, minerals, and nutrients are lost from every construction site. About 80 percent of the erosion in FLORIDA is due to manmade activities. Cutting the forests and plowing the land has also contributed to erosion of the land.

Human activities cause topsoil to be lost, along with the minerals and nutrients it contains. This affects agriculture. Erosion causes ugly gullies in the landscape. Materials from water erosion can clog culverts and streams. Recreational areas and residential areas are damaged by erosion. Wildlife may be destroyed and its environment altered to the point that it can no longer support wildlife.

Water erosion includes stream erosion, beach erosion, and erosion by flooding. Stream erosion is most common. Streams carry sediment from one place to another. The amount of sediment carried and the amount dropped depend on the speed of the water. Water speed is affected by many factors, including the steepness of the slope and the shape of the channel through which the stream flows. The faster the water moves, the more material it can carry, and the larger particles it can move. When water goes around a bend, sediment is removed from the outer part of the bend and swept downstream. Water flows more slowly on the inside of the curve, so sediment accumulates here as it is dropped by the slowing water. Valleys eroded by streams are V-shaped, as opposed to the U-shaped valleys eroded by glaciers.

Heavy rains in spring can increase the velocity of a stream and cause more erosion to take place. Sandy ground erodes more easily than rocky ground. At its most extreme, stream erosion has created wonders like the GRAND CANYON. This vast canyon was eroded by the Colorado River, although some scientists now believe other rivers helped cut the canyon. The canyon, which is 227 mi (446 km) long, averages 4,000 ft (1,219 m) deep. Its deepest point is 6,000 ft (1,829 m) and the widest point spans 15 mi (24 km). This erosion took place over a period of millions of years.

Beach erosion occurs along ocean shores and can be caused by natural phenomena or by humans. Natural phenomena that can cause beach erosion include currents, storms, earthquakes, winds, waves, and tides.

*Coastal erosion can cause millions of dollars in property damage, as shown after a coastal storm in Australia.*

The gradual movement of the Earth's tectonic plates can also cause beach erosion.

Unlike stream erosion, which takes place over a period of many years, beach erosion can be immediate. This is especially true in the case of a storm. However, even in calm weather, sand may be pulled out into deeper water, causing it to be lost from the beach. Loss of sand is significant, since the beach both protects the land behind it and provides recreation areas and habitat for wildlife. The beach absorbs energy from the sea, and the wider the beach is, the more energy it will absorb before the waves reach landward developments. So when sand is washed away, making the beaches recede, more damage is likely to be done to houses and developments.

Global warming also has its effect on beach erosion. It causes the sea to warm up and the polar ice caps to melt. This raises the level of the oceans, causing more erosion.

Many houses in Florida have been built too near the beach and erosion has put them at risk. The Cape Hatteras Lighthouse on the Outer Banks of NORTH CAROLINA is another example of buildings endangered

by erosion. When the 4,800-ton (907-kg) lighthouse was built in 1870, it was 1,500 ft (457 m) from the ocean. By 1999, the beach had been eroded to within 150 feet (46 m) of the structure. The Cape Hatteras Lighthouse was moved a quarter of a mile (.4 km) inland from its former site.

In MASSACHUSETTS, Cape Cod's oldest lighthouse, the Highland Light, is also threatened by beach erosion. The ATLANTIC OCEAN is 400 ft (122 m) closer than it was when the lighthouse was constructed in 1797. And in just the seven years between 1997 and 2004, 40 ft (12m) of beach disappeared because of harsh winter storms. The lighthouse now stands just 100 feet (30.5) from the water. The Army Corps of Engineers is in the process of moving the Highland Light, a \$1.5 million project.

### SEA WALLS

Man has tried to curtail beach erosion in several ways. Seawalls have been built off the shore. However, the walls reflect the wave energy back to the sea, and that accelerates erosion. Also the beaches don't get the sand that is usually eroded from the bluffs along the shore. Groins, which are rock walls built perpendicular to the beach, have also been tried. The sand will gather on the updrift side of the wall. The currents carrying sand are slowed down and slow-moving water can't carry as much sediment. The result is more sand on the updrift side, but it is removed from the downdrift side. Jim O'Connell, a coastal processes specialist at Woods Hole Oceanographic Institute, points out that the coastline is "all one linked system. If you alter one area, you will be causing an alteration in another."

On some beaches, restorers have tried pumping sand, obtained from deep waters, onto the beaches. It works for a while but is expensive. Robert Dalrymple, a civil engineer at the University of Delaware Sea Grant program calls it the "method of choice these days."

### BREAKWATERS

Building offshore breakwaters is another possible solution. These are long heaps of rocks dumped parallel to the shore to intercept waves. "Depending on how they are used, they will do fine," Dalrymple explained, but he also pointed out that visible breakwaters can be an eyesore. He says a submerged breakwater may be the solution, but details of where and how to build them have not yet been worked out.

Flooding can also cause erosion, and vice versa. When water overflows the banks of a river or lake, it can erode the land it covers. Flooding is also more

likely to occur where land at the edge of a river or lake has eroded away. Spring thunderstorms sometimes cause surface runoff and create large gullies when streams overflow their banks. Some flooding can be prevented. Flood prevention measures include digging drainage ditches, planting ground cover, constructing tile drains, creating and preserving wetlands, and building dams and levees.

Related to water erosion is erosion caused by ice. Most erosion by ice occurred during the Ice Ages, when the glaciers moved huge amounts of soil and rock. Hundreds of lakes were created as the glaciers moved slowly across the Northern Hemisphere. Glaciers also built up landforms when they melted, depositing rock, soil, and other materials. Most glacial erosion occurred during the Ice Ages, but glaciers still exist in ANTARCTICA, GREENLAND, CANADA, NEW ZEALAND, CHILE, and the northwestern UNITED STATES.

Another form of ice erosion occurs each winter when water trickles into cracks in rocks, then freezes. Since water expands when it freezes, the cracks are enlarged and the rocks continue to break down.

Water isn't the only thing that causes erosion. Wind erosion is also a serious problem in many parts of the world, especially in arid or semiarid regions. Agriculture suffers from the effects of wind erosion. During the 1930s, the Great Plains of the United States were subject to disastrous dust storms because of a long dry spell. This period in American history caused great hardship for the people who lived in that area, called the Dust Bowl. Although the Dust Bowl was the worst case of wind erosion, much land in the Great Plains was damaged by wind erosion as recently as 1996.

When wind erosion occurs, the lighter, less dense soil near the surface is removed. This is the most fertile part of the soil, so the land is then less productive. Blowing soil can also damage small plants. The dust fills the air, causing poor visibility and pollution. In the United States, wind erosion affects the Great Plains more than any other region, but it is also a serious problem in sandy coastal areas and in cultivated soil everywhere. After the Dust Bowl crisis, experts in prairie agriculture began searching for ways to control and prevent wind erosion. A lot of progress has been made. There are three basic objectives when trying to prevent wind erosion. First, you need to reduce the wind velocity at the surface of the soil. This can be done by planting windbreaks, leaving crop residues in the fields, planting cover crops, and increasing the roughness of the surface. Trapping soil particles is also

*At its most extreme, stream or river erosion has created wonders like the Grand Canyon in the United States.*

important. Ridging or roughening the surface of the soil will trap soil particles so they can't blow away. The third objective is to increase the size of the soil aggregates, which means creating clods on the soil's surface. Then it will take a stronger wind to move the larger chunks of soil.

Maintaining plant cover for the soil helps accomplish these objectives. Bare fields are especially at risk for wind erosion. Farmers often leave stubble standing in the fields over the winter. This helps prevent wind erosion, reduces evaporation, and traps snow, which provides extra moisture for the soil in spring.

Erosion isn't all bad, though. Without it, we wouldn't have sandy beaches, as the sand is made up of particles eroded from the rocks and soil along the coast. All soil is also made from the weathering of rocks. Erosion by glaciers gave us many of the lakes we enjoy for recreation and fresh water. Glaciers scooped out depressions that filled with water, creating the Great Lakes and many smaller lakes.

## escarpment

IN GEOLOGY, an escarpment is a steep edge of a ridge or cliff, characterized by an abrupt transition in altitude between two relatively level but differently composed series of sedimentary rocks, differing in age and composition. Escarpments, also known informally as “scarps,” are usually representative of the line of erosion of newer rock over the older rock and can exist both on dry land and below water. Escarpments are types of precipitous cliffs that can be formed by faulting of land or erosion by the elements of weather such as wind, water, or ice and are likely to be formed of limestone, sandstone, chalk, granite, and basalt.

Studies performed on various escarpment samples show that, in many cases, they were formed as a result of a process of erosion dating back over millions of years. Depending on circumstances, most escarpments have developed by erosion of ice dating back to the Ice Age or of water from the melting of glaciers and flows of streams. In some cases, more than one escarpment can exist in the same place. In other cases, escarpments are eroded and further formed from the sliding movement of sediment under water, such as with oceanic water movement and submarine landslides.

Escarpments on land can serve as homes to a wide variety of trees, plants, and other organisms that have been forced there or that simply prefer to live on rocky areas. Dense colonies of organisms, algae, and fungi, previously thought to be found only in distant ecotones such as Antarctica, have been found to exist in many dry land escarpments.

Escarpment formations have also been found on other planets, such as in the mountains of Jupiter’s moon, Io. Geologists think escarpments have been formed from a combination of unstable land and volcanic stress.

Little by little, escarpments and cliffs are undergoing changes and erosions of a different kind as an ever-increasing number of people discover the wonders of

the outdoors through rock climbing. Often, as the climbers scale along the rock surfaces, they pull out plants and brush in order to make the climbing surfaces safer and easier to navigate. The removal of the fauna and flora, as well as the steady rate of climbers passing through, is progressively changing the face of many escarpments and natural landscapes around the world.

## esker

AN ESKER IS A LONG, narrow, often snakelike ridge of sand and gravel deposited on top of the ground where a glacier has retreated. Eskers often follow valleys and lowlands, although some can go uphill. Most eskers are a single ridge, but there are also braided ridges, which are similar in shape to river tributaries. The esker got its name from an Irish Gaelic word, *eiscir*, which means “ridge of gravel.” If they are viewed from the air, eskers stand out from the rest of the terrain. They often look like large railroad embankments. Eskers are made up of all sizes of fluvial materials, from fine grains of sand to boulders. Most material, though, is the size of gravel. The finer sediments are often found near the top of the esker, while the large boulders will be much deeper. Eskers usually have steep sides of 25–30 degrees.

Most eskers formed during the time when glaciers were melting and retreating. A tunnel formed in the ice within the glacier, and meltwater began to run through the tunnel like an underground river. The water carried sediment with it. As it slowed down in certain places, some of the sediment was dropped and began to fill up the tunnel. As the tunnel filled up, the pressure of the water eroded the ice above it to make room for the water to continue flowing. Therefore, the whole tunnel

seldom filled with sediment. When the glacier melted, the sediment in the tunnel was lowered to the ground. It followed the route of the underground river, which was usually perpendicular to the face of the glacier.

Most eskers formed in enclosed tunnels through which water flowed, but a few formed in ice-walled trenches that were open to the sky. Only in the channels that were closed by ceilings was the water able to flow uphill. This worked like water under pressure in the pipes of a water system. In the ice channels on top of the glacier, the sediment was let down to ground level as the glacier melted. Eskers range from a few meters high to over 250 ft (200 m) high. However, most are 100 ft (30 m) or less. Some are a few miles long, and others can be as long as 311 mi (500 km). Scientists believe that a very long esker probably did not form as one event but is made up of many individual eskers formed together during the retreat of the ice sheet.

Most eskers consist of a long, continuous ridge, but some have breaks in them. This happened because in some places, if the water was flowing more quickly, no sediment was deposited. Sediment was laid down when the speed of the water slowed down. Some eskers are known as “beaded eskers.” They have a regular pattern of narrowing and widening out. This is believed to have been due to the fact that more sediment was deposited in summer than in winter.

Through the years, eskers have served several purposes. Since they are raised above the surrounding terrain and are often more firm than the land around them, they have been used as road beds. In IRELAND, the Eiscir Riada is still used as the base of Highway N4/NM6 from Dublin to Galway. The land around it is boggy, so the esker provides a firm foundation for the road. In the wilderness, wildlife typically use eskers as travel routes. Eskers have also been used as graveyards and golf courses. Recently, prospectors have used eskers to predict where diamonds will occur. Bush pilots flying over the Canadian wilderness often use eskers to guide them. The largest eskers in the world are found in the Canadian provinces of Nunavut, Manitoba, Quebec, and Labrador.

Many eskers have entirely disappeared, though, because the gravel that made up the esker has been excavated and used to build roads. Where a gravel pit has been dug in an esker, scientists are able to study the internal structure of the esker.

## Estonia

**Map Page** 1130 **Area** 16,852 square mi (43,211 square km) **Population** 1,408,556 **Capital** Tallinn **Highest Point** 1,050 ft (318 m) **Lowest Point** 0 m **GDP per capita** \$10,900 **Primary Natural Resources** oil shale, peat, phosphorite, clay, limestone, dolomite.

FOR CENTURIES DOMINATED by its larger and stronger neighbors, since independence from the former Soviet Union in 1991, the small country of Estonia has shown itself to be the economic tiger of the former communist countries of Eastern Europe. The smallest of the three Baltic states, Estonia was the first to reintroduce its own currency and has managed to reduce inflation from 1,000 percent in 1992 to 2.8 percent in 1999 and unemployment to a mere 3.3 percent, well below the EUROPEAN UNION (EU) average. Having joined the NORTH ATLANTIC TREATY ORGANIZATION (NATO) in 2002, Estonians embarked on a new course, firmly directed toward the West, with membership in the EU dating from May 1, 2004.

Estonia is closely tied to the Baltic region, with a long coastline (2,618 mi or 3,794 km), including its northern coast on the Gulf of Finland and over 1,500 islands in the Baltic Sea. The largest of these are Saaremaa and Hiiumaa. Its neighbors include RUSSIA to the east, and LATVIA to the south, with FINLAND a short distance across the gulf (about 53 mi or 85 km) at its closest. Historically, the region was connected to other Baltic powers through sea commerce and the economic expansion of German merchants during the Middle Ages. Estonia's towns were essentially German for most of their history as members of the vast Hanseatic League, including its main city of Tallinn, formerly known as Reval. The area formed a province in the

changing empires of the region, either Danish, German or Swedish, and finally Russian from 1721. The Estonian people themselves, sharing ethnic and linguistic affinity with the Finns (and, more distantly, Hungarians), generally populated the countryside and served as the agricultural labor force supplying the industry and trade of the Germanic towns. In the 19th century, however, Estonian nationalism stirred and began to clamor for an independent Estonia for Estonians. Yet as late as 1914, the so-called Baltic Barons, German noble landowners, still owned 90 percent of the large agriculture estates (60 percent of the total land) and dominated the cities as they had done since the Middle Ages. With GERMANY's defeat in 1918, Estonia declared itself independent, but this was short-lived, and the country was occupied by the Soviet Union in 1940, and formally declared a Soviet socialist republic.

The terrain is mostly flat and marshy in the north and west, becoming more hilly in the south and east. Bogs and wooded swamps cover a fifth of the country, and there are over 1,500 lakes. The largest of these lakes form part of the border with Russia, Lake Peipus and Lake Pskov. These lakes are connected by a channel, and flow out toward the Gulf of Finland through the Narva River. Võrts-Järv is a large inland lake whose waters flow eastward into Lake Peipus, passing by Estonia's second-largest city, Tartu.

### ESTONIAN INDUSTRY

The Narva corridor is also the center of Estonia's heavy industry, highly developed under the Soviet regime, with more investment per capita from Moscow than any other part of the Soviet Union. Estonian industry was geared to production of oil—from one of the world's largest deposits of combustible shale—and also military supplies. Leningrad, roughly 245 mi (395 km) away, became dependent on Estonia for gas and oil, but also relied on Estonia's fertile soils and dairy farms for its food needs, much as the city had done (as St. Petersburg) since its founding in the early 18th century.

Estonians remain wary of the large Russian population still living in Narva, while it converts the remains of the Soviet military industry to more useful products. Estonia has a very low population density, allowing much of the land to remain cultivated in small farms or left wooded for the second-largest economic activity, timber, paper, and furniture. Approximately one-third of the population lives in Tallinn. The fastest growth is occurring in service industries, such as tourism, trade and banking, and Estonia is becoming famous as a leader in e-government.

SMITHSONIAN INSTITUTION

## Ethiopia

**Map Page** 1114 **Area** 435,184 square mi (1,127,127 square km) **Population** 66,557,553 **Capital** Addis Ababa **Highest Point** 15,158 ft (4,620 m) **Lowest Point** -410 ft (-25 m) **GDP per capita** \$700 **Primary Natural Resources** precious metals, natural gas.

ETHIOPIA IS LOCATED in northeastern Africa, an area rich in geography, climate, and history. The Great Rift Valley, which extends across most of east Africa, bisects Ethiopia's central mountainous plateau, providing the country with highlands, mountains, plains, and climatic diversity. The heaviest rains occur in the summer months with a lighter rainfall in the spring, when the monsoons arrive from the INDIAN OCEAN. Rains in the south and southwest of the country are nearly continuous over the year, moderating temperatures in the highlands, where most of the population lives, and leaving the eastern plains drier and hotter. The capital, Addis Ababa, is located at 8,000 ft (2,450 m), with average yearly temperatures of 68 degrees F (17 degrees C).

The nation's major river, the Blue Nile, is fed by runoff from the western portion of the plateau and flows toward the NILE and SUDAN to the west. Ethiopia's forests and wooded areas are concentrated in the southwest, and are centers of coffee production, while cattle are grazed on the grasslands. Despite its climate, Ethiopia faces severe deforestation and DESERTIFICATION problems, mainly caused by the civil war, drought, and famines.

Ethiopia is rich in human history. The earliest known hominid, "Lucy," was unearthed in 1974 near Addis Ababa and was dated to 3.5 million years ago. Archaeological research indicates continuous human habitation for the past 2 million years. Neolithic civi-

lization entered Ethiopia from EGYPT and the RED SEA, indicating a trading network that connected the area to the Mediterranean and Arabia. Traditional Ethiopian history started when the Queen of Sheba, purportedly from Ethiopia, visited King Solomon in the 10th century B.C.E. Historically, however, Ethiopian history originated in the second millennium B.C.E. under the influence of the Egyptians and later Greeks. An independent Ethiopian civilization emerged in the 1st century C.E. in Aksum and its seaport, Adulis. The Aksumite kingdom traded with the peoples of the Red Sea and interior of Africa.

In the 4th century C.E., Greek missionaries introduced Christianity from Alexandria, EGYPT. In 451, exiled Greek and Syrian monks established Monophysite Christian communities throughout the kingdom furthering the influence of the Egyptian Coptic rather than the Roman Catholic Church. In 525, the Aksumite king, responding to a request from Emperor Justinian I to aid persecuted Yemeni Christians, invaded and occupied the southern portion of the Arabian Peninsula until the Aksumites were expelled by the Muslims at the end of the century. The Aksumites, however, used their expanded holdings to trade with INDIA and maintain communication with the Byzantines.

This period of expansion was not long lasting because by the middle of the 7th century, Islamic invaders from Arabia conquered Egypt, isolating the Auxites from the broader Christian world. Isolation meant a gradual political decline over the next 300 years, with central authority collapsing in the 10th century. Ethiopia entered a period of warring chieftains and provincialism. Finally, in the late 13th century, the Solomonic dynasty, so named after its lineage to King Solomon and the Queen of Sheba, reestablished central authority with the new dynasts claiming the title of Negus Negusti, king-of-kings. The kingdom consolidated political and military power and expanded against a series of smaller Muslim principalities to the south. During this period of renewed expansion, Europeans reestablished contact with the Christian Ethiopians.

In 1490, Portuguese explorers searching for the legendary Christian kingdom of Prestor John arrived and subsequently aided the Ethiopians against the Muslims. Relations with the Europeans soured when the Portuguese tried to pressure the Ethiopians into accepting Roman Catholicism. The Ethiopians then expelled the Europeans and enacted a strict isolationist policy, which lasted until European imperialism encroached into Africa during the 19th century.

In 1869, Italian imperialists purchased the nearby Red Sea port of Assab from the Egyptians. In 1882, Italy acquired the surrounding territory and merged their holdings into a single colony. Not satisfied, the Italians expanded northward along the coast into territory claimed by the Ethiopian kingdom. To avoid potential conflict, the Italians and Ethiopians agreed in 1889 that Italy could expand into limited areas of northern Ethiopia. Tensions mounted, however, after Italy formed the colony of ERITREA and became involved in a dynastic struggle in Ethiopia. The tensions touched off a native uprising in Eritrea, leading the Italians to invade Ethiopia hoping to end any aid given the native Eritreans by Ethiopia.

The Ethiopians soundly defeated the invaders in 1896 at the Battle of Adowa, thereby ensuring the empire's continued independence from European imperialism until well into the 20th century. The Italians vowed revenge, and in 1935 the Italian fascist regime invaded and conquered Ethiopia. Emperor Haile Selassie fled to Great Britain and remained in exile until the Allies liberated Ethiopia and Eritrea in 1941. Selassie returned to power and in 1952 ruled over a federal system of Ethiopia and Eritrea until the early 1960s, when he annexed Eritrea.

In 1974, the Derg, a military council, overthrew the emperor and eventually imposed a totalitarian regime with Soviet aid. In 1991, the rebel Ethiopian People's Revolutionary Democrat Front, a coalition of the various domestic opposition groups, overthrew the government and promulgated a new constitution. Under pressure from ethnic minorities for more local government, the new government subdivided the nation into nine provinces with a legislative assembly.

## Ethiopian Highlands

ETHIOPIA IS A LANDLOCKED nation located in northeastern Africa in an area known as the HORN OF

AFRICA. While containing large stretches of plains in the east and south, the country is dominated by highlands, which rise to well over 3,000 ft (1,300 m), and the Great Rift Valley, which is several hundred meters below sea level. Elevated plateaus compose much of the geography in northeastern Africa, an area close to the RED SEA, which encompasses both ERITREA and ETHIOPIA. Likewise, the Great Rift, formed 50 million years ago by volcanic activity, also extends across most of eastern Africa and bisects Ethiopia's central mountainous plateau from roughly the southwest to the northeast, creating two highland areas. The largest, the western side, is known as the Ethiopian Plateau and is the higher of the two, with the tallest peak, Ras Dashan at 15,158 ft (4,620 m). Located in the Simen Mountains, the peak is located southwest to two similar, though slightly less imposing mountains. Aside from being among Africa's highest mountains, the area is also the source of the Blue Nile, Lake Tana.

Land on the eastern plateau slopes in a generally westerly direction and provides much of Sudan, and ultimately the NILE, with water. The smaller, eastern plateau extends toward the Gulf of Aden, on the INDIAN OCEAN, and divides the lowlands to the east, near Somaliland, from the Danakil Desert by the Eritrean border. The verticals of both plateaus are very impressive.

In the center, the Great Rift rises at almost a vertical to both heights. The eastern spur, however, is generally more gradual than the Ethiopian plateau in the west and slopes into the surrounding desert. Water erosion has created impressive cuts throughout the highland; vertical drops of many thousands of feet are common. In addition, the same erosion has created smaller plateaus, known as *ambas*, which are the sites of many of the nation's important battles and monasteries.

The highlands obviously have influenced Ethiopia's climate, demographics, and history. Despite being so close to the equator, Ethiopia has a quite moderate climate largely because of its heights. Outside of the Danakil depression, the Great Rift Valley floor, and the eastern plains, which are primarily desert, Ethiopia's climate varies from alpine, in the higher mountains, to moderate. The capital city, Addis Ababa is located at 8,000 ft (2,450 m), with average yearly temperatures of 68 degrees F (20 degrees C).

Winter, which can be very brutal in some higher areas, lasts from October to February. Spring is generally drier, though some rains do occur. The heaviest rains fall in the summer months, from June to mid-Sep-

tember, and taper off in the autumn months. Given the relative heights and sloping of the highlands, and the amount of water it receives, there are numerous lakes and rivers. Most of the forests are in the southwest, while the plateau highlands contain scattered copses and GRASSLANDS. Fauna in the highlands are mainly domestic animals, such as cattle, which graze on the grasslands, and birds, large cats, hyenas, and wolves.

Early human habitation started out in the Rift Valley, with the oldest human ancestor being found there in 1974. Over time, habitation expanded to the highlands, providing people with rich soil and grazing space for their animals. One of the first Ethiopian civilizations arose in the northwest plateau, at Aksum. Over time, the highlands, including portions of northern and northwestern Eritrea, were incorporated into various Ethiopian Christian kingdoms, often at war with the Muslims in the eastern lowlands. The highlands protected Ethiopia from many foreign invasions, particularly from the Italian colony of Eritrea in 1896. At the Battle of Adowa, fought in the highlands just south of the Eritrean border, the Imperial Army of Ethiopia destroyed an Italian-led Eritrea force. The highlands, however, were unable to completely protect against the Italian invasion of 1935.

## European Union

THE EUROPEAN UNION (EU), with 25 member states in 2004, had its initial organization created after World War II for the purpose of rebuilding Europe after the turmoil and devastation of the war. It was thought that economic and political cooperation would greatly reduce the risks of repeating such a conflict and would be the first step toward unifying European interests.

The idea was to create an internal market in order to enhance economic growth. Created as a predecessor organization in 1951 with six countries, what became the European Union has added countries to the consortium four times, and in 2004 was preparing for its fifth expansion. The EU benefits consumers (lower prices,

greater choice of goods and services, work conditions within the EU) and businesses (fair competition, economies of scale, expansion to global markets).

The European Union comprises countries in the continent of Europe, bordered on the west, north, and south by the ATLANTIC, ARCTIC, and MEDITERRANEAN oceans and seas. The eastern border of the continent, however, is to some extent vague. Some people believe that the URAL MOUNTAINS of RUSSIA, the Ural River and the CASPIAN SEA are the eastern border of Europe. Others believe that the border with Russia is Europe's eastern boundary, while some others separate Europe from Asia by the Bosphorus Strait.

As a continent, Europe is relatively small. Its physical landscapes, however, are varied and complex. The countries in Europe differ in climate, vegetation, and elevations: From the warm and dry Mediterranean climates in southern Europe, to the frigid climates of northern Scandinavia; from the moist woodlands of Western Europe, to the dry STEPPES in the eastern extremities of Europe; and from the flat coastlines of the NORTH SEA, to the majestic ALPS.

The formation of the European Union began with six countries: BELGIUM, GERMANY, FRANCE, ITALY, LUXEMBOURG, and the NETHERLANDS. After nearly 50 years, four different expansions included: 1973: DENMARK, IRELAND, and the UNITED KINGDOM; 1981: GREECE; 1986: SPAIN and PORTUGAL; 1995: AUSTRIA, FINLAND, and SWEDEN; 2004: CYPRUS, CZECH REPUBLIC, ESTONIA, HUNGARY, LATVIA, LITHUANIA, MALTA, POLAND, SLOVENIA, and SLOVAKIA. The next expansion is scheduled to occur in 2007, with BULGARIA and ROMANIA joining the EU. The countries of CROATIA and TURKEY have also applied for membership but have not been accepted for the 2007 expansion.

Other milestones of the enlargement of the European Union include the following:

1952: The European Coal and Steel Community (ECSC) was founded by Germany, France, Italy, the Netherlands, Luxembourg, and Belgium.

1958: The European Economic Community (EEC) and Euratom were founded. The EEC was a community in which free trade for all products was established. Euratom dealt with research, production, and safety in the nuclear energy sector.

1967: The three organizations (ECSC, EEG, and Euratom) were merged into the European Community (EC).

1991: Maastricht Treaty (the Treaty of the EU) goes beyond the internal market program and includes additional areas in the integration process.

1993: The EC was renamed European Union.

1997: The Amsterdam Treaty was signed.

The total geographic area of the EU is 2,419,064 square mi (6,265,347 square km), and if it were a country, it would be the seventh-largest in the world by geographic area. The number of EU citizens (all member state citizens or subjects, under the terms of the Maastricht Treaty) is about 453 million (March 2004). The population of the EU, considered as one country, would be the third-largest in the world after INDIA and CHINA. Germany has the largest population, with 82.5 million inhabitants and Malta is the smallest, with 387,000 people. Many countries, such as MONACO and ANDORRA, while not being member states, have special agreements with the EU. Other areas have connections or associations with EU member states through a colonial past, cultural links, or geographic placement: GREENLAND, the Isle of Man and the CANARY ISLANDS.

The addition of countries to the EU raises issues about how the member countries are affected. Specifically, economists consider the implications for southern European countries (Spain, Italy, Portugal, and Greece) which are major beneficiaries of EU's redistribution programs. The enlargement of the EU not only effects change in economic geography, it creates change in the political landscape (national sovereignty and political governance) and cultural geography.

## LARGEST ECONOMY

In 2004, the EU had the largest economy in the world. The EU continues to have an import surplus, contrasting the widening trade deficit that affects the United States. However, in 2004 the EU had stagnant economic growth with low employment. It is anticipated that the gross domestic product per capita of the whole EU will fall over the short-term. In the long-term, the EU's economy will suffer from significant demographic challenges.

The EU has no designated capital city, but Brussels is the de facto administrative center, as it is the home of the European Commission, the Council of Ministers and the European parliamentary commissions. The European Parliament sits in the French city of Strasbourg while Luxembourg is the seat of the European Court of Justice and parliamentary offices.

As the changing name of the EU (from European Economic Community to European Community to European Union) suggests, the EU has evolved over time from a primarily economic union to an increasingly political one. This trend is highlighted by the increasing number of policy areas that fall within the EU areas of

interest. Political power has tended to shift from the member states to the EU.

This picture of increasing political focus can be illustrated by two points. First, some member states have a domestic tradition of strong regional government. This has led to an increased focus on regional policy in the European regions. A Committee of the Regions was established as part of the Treaty of Maastricht. It led to the formal creation of the EU and was the result of separate negotiations on the Monetary Union and on the Political Union.

### THE EURO

The Treaty of Maastricht led to the creation of the euro (the European currency) and introduced a three-pillar structure (the Community pillar, the Common Foreign and Security Policy, or CFSP, pillar, and the Justice and Home Affairs pillar). There was a desire to focus the EU on the areas of foreign policy, security and defense policy, asylum and immigration policy, police cooperation, and judicial cooperation. Within each pillar, a different balance is struck between the supranational and intergovernmental principles.

Originally, the European Community was essentially concerned with economic and trade matters. The European Commission and the European Court of Justice were both independent from the EC governments and had a lot of power within the system. The European Parliament, which was directly elected by the citizens of the EC member states, also had some limited power.

Additionally, EU policy areas covers a number of different forms of cooperation: 1) autonomous decision making; 2) member states laws are harmonized through the EU legislative process, which has resulted in EU laws becoming increasingly present in the systems of the member states; and 3) member states agree to coordinate their domestic policies.

The tension between EU and national (or sub-national states) is an enduring one in the development of the organization. All prospective members must adopt, implement, and enforce legislation in order to bring themselves into line with the common European legal framework. The entire body of European laws is known as the “Acquis Communautaire.” This includes all the treaties, regulations, and directives passed by the European institutions as well as judgments issued by the Court of Justice. The EU is characterized by sharing a broad number of issues and covering specific issues in the internal market and its external relations. With respect to the single market internal aspects, the

main principles are the free movement of goods, services, persons and capital (a goal further extended to some countries by the European Economic Area, EEA); a common EU competition policy controlling anti-competitive activities of enterprises (antitrust, abuse of dominant market position, merger controls) and member states; and freedom for citizens of its member states to move, live, and work anywhere within the territory of the member states, provided they can support themselves (also extended to other EEA states).

The last has resulted in the elimination of checks on individuals at the borders between EU member states. The Schengen Treaty authorized the elimination of internal border controls and coordination of external controls between its member states. This excludes the United Kingdom and Ireland, which have continued to check all persons entering their borders. In addition, two non-EU countries—ICELAND and NORWAY—participate through special agreements.

The EU seeks policy coordination in a changing regulatory environment. This effects government regulation, corporate law, and trademark registrations by lowering administrative costs, stimulating cross-border business cooperation, and creating greater attractiveness for outside investors. The single currency, the euro, has been adopted by all member states except the United Kingdom, Denmark, Sweden, and the last 10 countries that entered the EU in 2004. The adoption of a single currency is the final part of the Economic and Monetary Union (EMU). The first stage was to remove barriers to free-up the movement of capital, and the second stage was to set up the European Central Bank. Stage three consisted in the introduction of the euro currency and its adoption by most part of member states at the start of 2002.

The EU promotes common agricultural policies (CAPs). The CAP was established in the late 1950s as a response of food shortages in Europe. Today, CAP addresses other problems (overproduction, sustainability of agriculture and food). CAP expenditure accounts for approximately 45 percent of the EU budget.

The EU also establishes a common system of indirect taxation, the VAT (value added tax), as well as common customs duties and excises on various products. It provides resources for the development of disadvantaged regions (structural and cohesion funds). With regard to the external issues to the internal market, the EU forms a customs union with a common commercial policy vis-à-vis countries outside the EU. This policy is pursued within the World Trade Organization regulations. Further, the EU provides resources

*The enlargement of the European Union not only effects change in economic geography, it creates change in the political landscape (national sovereignty and political governance) and cultural geography.*

for programs in candidate countries and other Eastern European nations, as well as aid to several developing nations.

For the future, the EU is considering the possibilities of EU citizens voting on local government and European Parliament suffrages in any member state;

collaboration in criminal issues, comprising intelligence issues through the European Police Office (Europol) and the Schengen Treaty; a unique foreign policy for all EU member states; and a common security policy, including the creation of 60,000-member European Rapid Reaction Force (ERRF) for peace-keeping and conflict prevention purposes.

The EU is in many ways a unique phenomenon. The EU institutions do not exclusively reflect the characteristics of supranational institutions, but rather a combination of both intergovernmentalism and supranationalism. An essential tension exists within the EU between intergovernmentalism and supranationalism. The final goal of intergovernmentalism is the protection of sovereignty (power is possessed by member states and decisions are made by unanimity). An alternative method of decision making in international organizations is supranationalism. This denotes a framework in which supranational factors possess a significant impact on the member states (member states still have power, but they must share this power with the other member states).

This institutional challenge is probably the greatest of all challenges facing the EU. Intergovernmentalism has historically been preferred by France, and by more Euro-skeptic countries such as the United Kingdom and Denmark, while more integrationist nations such as Belgium, Germany, and Italy have tended to favor the supranational framework.

## Everest, Mount

A PEAK ON THE CREST of the Great Himalayan range in Asia, Everest is the highest point on the Earth. It lies in the Central HIMALAYAS on the border between NEPAL and CHINA (Tibet). Three barren ridges, the south-

east, northeast and west culminate in two summits at Everest (29,028 ft or 8,848 m) and South Peak (28,700 ft or 8,748 m). The mountain can be seen directly from its northeastern side where it rises about 12,000 ft (3600 m) above the plateau of Tibet. It claims an incredible view from the top. The formerly accepted elevation of 29,028 ft (8,848 m) established in the early 1950s was recalculated in the late 1990s as 29,035 ft (8,850 m). Its identity as the highest point on the Earth's surface was not recognized until 1852, when the Survey of India, a government organization established that fact. In 1865, the mountain, previously referred to as Mountain Monarch or Peak XV, was renamed for Sir George Everest, a Welshman, who was the surveyor general of India from 1830 to 1843.

The summit itself consists of rock-hard snow; surrounded by a layer of snow that fluctuates annually by some 5 to 7 ft (1.5 to 2 m). It is highest in September and lowest in May, after depletion by the strong northwesterly winter winds. Though the exact thickness of snow atop Mount Everest remains a mystery for scientists around the world, the measure taken by an Italian mountaineering team was more than 8 ft (2.5 m). Individual glaciers around Mount Everest are the Kangshung Glacier (east), Rongbuk (north and northwest), the Pumori (northwest), the Khumbu (west and south) and an enclosed valley of ice between Everest and the Lhotse-Nuptse ridge. The mountain's drainage pattern radiates to the south, west, north, and east. The glaciers melt into rivers flowing towards Tibet and Nepal. Precipitation falls as snow during the summer monsoons (May to September). Lack of oxygen, powerful winds, and extremely cold temperatures preclude the development of any plant or animal life on the upper slopes. At the summit of Mt. Everest, atmospheric pressure is only 30 percent that of sea level, so the climbers take in only 30 percent as much oxygen (and thus need to carry oxygen tanks). There are no permanent settlements here because no one can adjust year-round to such high altitudes.

Attempts to climb Everest began with the opening of the Tibetan route in 1920. Everest was finally surmounted in 1953 as a result of efforts by an expedition sponsored by the Royal Geographical Society and the joint Himalayan Committee of the Alpine Club. On May 29, 1953, Edmund Hillary and Tenzing Norgay became the first to reach the top of the world's highest peak. Since then, 1,200 men and women from 63 nations have reached the summit. Nearly 200 others have perished in the attempt. Japanese woman climber Junko Tabei in 1975 became the first woman to sum-

mit Everest. The South Col route to Everest is the most popular and used by more climbers than any other path. The north ridge route begins in Tibet. At the foot of Mount Everest, Rongpu Gumpa is the highest monastery in the world. The local people revere the mountain. Its Nepali name (Sagar matha) and Tibetan name (Qomolangma) mean “Goddess mother of the world.” The Sherpas, an ethnic group of the Khumbu valley beneath Everest, urge their clients to ask the mountain deity’s blessings with offerings of rice and incense at base camp. Buddhist legend holds that Everest is home to a goddess bearing a bowl of food and a mongoose spitting jewels. Everest has indeed brought prosperity to the region.

The first ascent of Mount Everest sparked a tourism boom that draws more than 20,000 visitors each year to hike amidst the planet’s tallest peak. The 50th anniversary of the first ascent of Everest was celebrated in May 2003. Efforts at cleaning up the Everest slopes started in 1994, and more than 20,000 pounds of garbage have been hauled off the peak. Sherpas are paid to bring down used oxygen bottles and other trash.

A Chinese survey has revealed that the world’s highest peak is gradually losing its height because of global warming and the shrinking of glaciers in the Himalayan region. According to a scientific survey report released at a recent international symposium held in Lhasa, Tibet, the mountaintop declined by 4.2 ft (1.3 m) in the 33 years ending in 1999. Global warming accelerates the process of conversion from snow to ice.

PRABHA SHASTRI RANADE  
JAWAHARLAL NEHRU UNIVERSITY, INDIA

*Everest's formerly accepted elevation of 29,028 ft (8,848 m) was recalculated in the late 1990s as 29,035 ft (8,850 m).*

whenever we use the wheel, look at the clock or our watches to tell time divided into units of 60, or view our calendars as a revision of the method the ancient Egyptians used in dividing the year. Our inheritance in both experience and knowledge from the past is far more than we know or realize.

No one knows exactly when humans began the transition from hunting and gathering to sedentary living. But we do find a very close relationship between the organization of humans in settled areas and the rise of agriculture and the domestication of crops. Agriculture had its most referenced beginnings at least 7,000 years ago in two great centers: one in the fertile alluvial plains of a land called Mesopotamia and the other along the lower reaches of the Valley of the Nile. We shall leave the interesting question of the precise area in which agriculture originated to the archaeologists. It is enough for us to know that it was in these alluvial plains in an arid climate that the first tillers of soil began to grow food crops using IRRIGATION in quantities that exceeded their own needs.

Where agriculture was practiced under especially favorable conditions, it was even possible to produce more food than the local inhabitants actually needed at any given time. The significance of being able to produce surplus food can scarcely be overemphasized, for by releasing some workers from the day-to-day chores of tilling the fields, it permitted a diversification and

## exotic rivers

THERE IS A WRITTEN record on the land in the Near East. Here, civilization arose out of the mysteries of the stone age and gave rise to cultures that moved eastward to CHINA and westward through Europe and across the ATLANTIC OCEAN to the Americas. Achievements of ancient origin serve as constant reminders of our debt to the Sumerian peoples of Mesopotamia

specialization of labor that had never before been possible.

Of course, the basic need behind all of this is water, for without water there is little evidence of life let alone society or civilization. Even today, we find more than 90 percent of the world's population living within 62 mi (100 km) of the coast or a major navigable river. It should also be pointed out that in the wake of surplus food production and the concomitant necessity for food storage, other modifications in the material culture of the peoples were almost inevitable hallmarks of such an advance. Vessels for storage, such as baskets and pottery, now became part of the inventory of the average household. And the latter, in particular because of its relative imperishability, has become a favored diagnostic tool of the archaeologist in tracing the economic evolution of a culture.

Although examples of preagricultural ceramics do exist, the more usual case is that they are evidence of a settled, farming society of greater complexity and sophistication. It was this organization of community (or place) around a multitude of functions that led Greek scholars to later conclude that cities grew up as a response to human NEEDS AND WANTS.

## RIVER CIVILIZATIONS

Historically, the archaeological evidence suggests that the first great civilizations were all river civilizations. Even more interesting is the fact that in each of these early cases, the lands on which these early civilizations took form were also very dry, DESERT or semidesert environments. Desert regions can be found on all continents and they occur in two zones, one on either side of the equator. One zone is found between 15 degrees N and 30 degrees N latitude and the other between 15 degrees S and 30 degrees S latitude. Most deserts are found on the western side of continents and extend inland. Only the Sahara Desert extends from one side of a continent to the other.

Though little rain falls in deserts, deserts receive runoff from ephemeral, or short-lived, streams fed by rain and snow from adjacent highlands. These streams fill the channel with a slurry of mud and commonly transport considerable quantities of sediment for a day or two. Although most deserts are in basins with closed, or interior, drainage, rivers that derive their water from outside the desert cross a few deserts.

These rivers receive a lot of rainfall (or snowfall) in the areas where they arise, that is, in the area known as their headwaters. This large supply of water allows them to flow across the desert even though a lot of

water is lost through evaporation into the atmosphere or through seepage beneath the desert surface. These rivers are called exotic rivers because the water they carry comes from outside the desert region they pass through. Such rivers infiltrate soils and evaporate large amounts of water on their journeys through the deserts, but their volumes are such that they maintain their continuity.

These older, specially favored areas of human habitation and food production have typically been found in the so-called exotic river valleys of the Near East, such as the Tigris and Euphrates in Mesopotamia (present day IRAQ), as early as 4500 B.C.E.; in the Nile Valley of EGYPT by 4000 B.C.E.; the Indus Valley of PAKISTAN by 3500 B.C.E.; the valleys of the AMU DARYA and Syr Darya in Central Asia by 3000 B.C.E.; and the HUANG (Yellow) and Wei river valleys of North CHINA by 2500 B.C.E. In every instance there was a desert climate with cloudless skies, lots of daily sunshine, little if any frost, little or no vegetation cover to clear, and rich alluvial soils coincided with a continuous supply of water from the adjacent river. Indeed, each of these exotic river valleys was either the cradle of a civilization in its own right or, at least, the beneficiary of a diffusion, which first began in Mesopotamia and was later emulated elsewhere under remarkably similar environmental conditions.

These so-called exotic rivers cross all of the large deserts of the world, except those of AUSTRALIA. Also, desert soils are usually quite productive when supplied with water. The most widely cultivated areas are where there are water-transported soils in the form of FLOODPLAINS and ALLUVIAL FANS.

There is good evidence that in the New World the model of "hydraulic" civilizations based on exotic rivers as described above may have been first replicated in the Atacama Desert along the west coast of PERU where about 40 short exotic rivers cut their way from the ANDES to the PACIFIC OCEAN. The other New World area where a hydraulic culture occurred was in the Colorado Plateau region of the southwestern part of the UNITED STATES (the southwest Anasazi culture), where the Colorado River cuts its way from the ROCKY MOUNTAINS across the plateau and into the Sonoran and the Mojave Desert before emptying into the Gulf of California. There are a number of examples of exotic rivers where civilization did not seem to take hold. These include the Snake River in IDAHO and parts of the Columbia River which cuts through desert landscapes of WASHINGTON and OREGON. There are no exotic rivers in Europe or Australia.

## facilities mapping

FACILITIES MAPPING (FM) is the process of digitally identifying and mapping facilities infrastructure with the explicit goal to improve operational management and planning tasks such as dispatching, inventorying, and maintenance. Some examples of facilities include utilities (gas, water, telephone, and electricity), airport siting, and transportation planning. In the past, when a facilities map was needed, a team of surveyors and draftspersons would combine skills to develop such a map. Usually the map was created and updated manually. Today, in the competitive business world of facilities service provision companies must continuously find new ways to maintain and deliver efficient services. This is a challenge as the facilities infrastructure is usually dense and covers large geographic areas. Moreover, time is also a key component. The steps for a successful operational strategy is based on collecting and integrating information on organization assets, processes, potential and existing customers, and changing market situations.

The core of the FM system is built around computer-aided drafting and design (CADD), geographical information systems (GIS), and global positioning systems (GPS) technologies. This combination of geospatial technologies has also caused some confusion in drawing disciplinary boundaries of FM. Hence, terms

such as AM/FM (automated mapping/facilities management) and network management systems are essentially the same technology. Because of the linear characteristics of the utilities infrastructure, CADD software is generally the choice for digital encoding. But there is the tendency now to merge CADD systems with the spatial data management capabilities of GIS in order to develop more integrated databases.

The encoded facilities infrastructures are then linked to a database that holds detailed attribute information about each facility. By querying the map on the computer screen, information about each facility and its relationship to other facilities can be obtained for operational planning and management purposes. Updates can be quickly made using a digitizing table, a mouse, and a keyboard. Usually the decisions made using FM are not for analytical purposes but for allocating resources for service dispatching, inventorying, and maintenance. Nevertheless, analytical studies such as network analysis and catchments area analysis are possible with FM systems.

Global positioning systems also play a major role in facilities management. The GPS is a network of 24 orbiting satellites and Earth receiving stations that provide an accurate and unique coordinate position for any point on the Earth's surface. The network was originally designed as a navigational tool for military applications, but the civilian and research community

has quickly realized the value of the technology and adopted it for use in many navigational applications. The satellites transmit signals that anyone can collect with a suitable GPS receiver. For example, with inexpensive GPS receivers, utility service crews can be quickly dispatched to the location of utilities needing repair.

### INTEGRATED TECHNOLOGY

FM has benefited tremendously from integrating CADD, GIS, and GPS technologies, the key benefit being to provide an integrated solution to business operational planning and management. The mapping capabilities of the FM system store information in different layers providing multiple ways of generating focused maps from a single and consistent database. Usually maps of multiple scales are available to address the task. For servicing, detailed maps showing the accurate location of facilities in need of repair are essential. For planning, coarse scale maps may be sufficient as only overall distribution of the facilities infrastructure may be of interest.

A centralized database of information streamlines data control, access, and updating, thereby creating an overall efficient search and query operation. Because the utility maps are digital, sharing of data and information among different agencies operating in the same area becomes a distinct possibility. The sharing of data reduces duplication of efforts, minimizes unnecessary damage to adjacent facilities, lowers maintenance costs, and improves customer service.

Facilities mapping is still evolving as new beneficial technologies continue to emerge and become integrated in the FM core system. Internet mapping is one technology that has begun to impact FM systems development. The internet provides a distributed medium to connect parts of the same company at one location or different locations. Wireless and mobile computing are already impacting FM in many ways. Field teams can receive customer calls directly and, with the aid of wireless and mobile computing devices, report to a service-outage location in real time.

Knowing about the availability of existing service resources in the area or planning repair strategies before arriving at the location are distinct advantages of mobile and wireless computing. As companies move away from rigid vertical management structures, distributed technologies will play an important role in maintaining customer satisfaction and the competitive edge necessary for survival in an ever-changing business climate.

MCGILL UNIVERSITY, CANADA

## Falkland Islands

THE FALKLAND ISLANDS, a British dependency contested by ARGENTINA, which calls them the *Islas Malvinas*, are located in the South ATLANTIC OCEAN near South America, approximately 300 mi (483 km) east of Argentina. The Falkland Islands consist of two main islands (East and West Falklands), which are divided by the Falkland Sound. There are more than 100 smaller islands that are part of the Falklands. The island of South Georgia, which is southeast of the Falklands, is a territory of the Falkland Islands. The islands have a population of 2,379, with most living near the capital, Stanley. Occupying 4,700 square mi (12,173 square km), the territory's highest point is Mt. Usborne at 2,312 ft or 705 m.

The Falkland Islands were discovered by the British in 1592 but not claimed by the British until 1690, when a detachment landed for the first time and named it after the first lord of the Admiralty of the time. In the 18th century, French settlers stayed for a short period, and SPAIN also claimed sovereignty. The emerging Argentine state called for the succession of the Spanish, but the British took over the islands in 1833. British settlers since then stayed continuously, although the sheep production made it an economically difficult enterprise in problematic weather conditions (not too far from ANTARCTICA).

The strategic importance of the Falkland Islands is due to their proximity to the southern parts of South America and Antarctica. The islands came twice to global awareness, both in the setting of armed conflict. In 1914, the British navy smashed the East Asian Squadron of the German navy in the Battles of Coronel and the Falklands. In 1982, the Argentine military government occupied the islands but was defeated by the British when Prime Minister Margaret Thatcher de-

cided to resist this military assault. The inhabitants of the Falklands are nearly all of British descent and they never embraced Argentine rule. The British campaign in the Falklands was formidable and outstanding in all its major elements (navy, air force and ground force), as the British won under arctic conditions on islands literally “on the other side of the earth” (from Britain), whereas the Argentine mainland was in close proximity to the battleground. The British victory in the Falklands War led to an overthrow of the military dictatorship because of popular unrest within Argentina, whereby this was a first step for reestablishing democratic regimes in the whole of South America.

Before 1982, the British government was probably not really interested in keeping the economically deficient islands, but this changed dramatically when the Argentines took it by force. The economy of the Falkland Islands was changed forever after the liberation from Argentine occupation, as the now necessary military presence of British troops needed heavy investment (especially a large airport). Traditionally a coaling and whaling harbor, the Falkland Islands undertook an economic development program for exploiting oil fields within the territorial waters of the islands and for expanding tourism. The role of the Falkland Islands and of South Georgia as a springboard for missions in Antarctica should not be underestimated.

The relations with Argentina are still tense, as the Falkland Islanders suspect a new Argentine attempt to take over the islands. Although the British government is unambiguous about not changing the sovereignty of the islands against the will of the inhabitants, the defense of the islands since the 1982 war has cost an enormous amount of British taxpayers' money.

## Faroe Islands

THE FAROE OR FAEROE Islands (Faerøerne in Danish, Farøyar in Faroese, meaning the “Sheep Islands”)

are located at the intersection of the North ATLANTIC OCEAN and the Norwegian Sea, roughly equidistant between NORWAY, SCOTLAND, and ICELAND. Their closest neighbors are the Shetland Islands, 190 mi (305 km) to the southeast. Like the Shetlands, the Faroes were first encountered and settled in the 9th century by Norwegian Vikings, but while the Shetlands were eventually given to Scotland, the Faroes remained part of the Kingdom of Norway, until 1814, when Norway was ceded by DENMARK to SWEDEN. The Faroe Islands (along with ICELAND and GREENLAND) remained a possession of the Danish crown and were given powers of self-government in 1948.

The group consists of 17 inhabited islands, including the main island of Streymoy (or Strømø in Danish) and one uninhabited island and islets. The other main islands are Eysturoy, Sandoy, Suderoy and Vágar. Altogether the coastline stretches 694 mi (1,117 km). The terrain is very rugged, with rocky peaks, and cliffs along most of the coast. Human habitation is thus limited mostly to narrow coastal lowlands. Although the islands are located very far north, the climate is surprisingly mild in the winters from the effects of the upper reaches of the GULF STREAM. Horses and sheep, for example, can winter in the open air. Summers are cool, and year-round skies are usually overcast, with an abundance of fog and wind.

The soil is generally very thin, but some crops can grow, including modest amounts of barley, turnips, and potatoes. There are little to no trees, but abundant turf, which is used for fuel. By far, the biggest industry is fishing and fish processing, with subsidiary industrial activity in shipbuilding and construction. Sheep rearing and dairying supplement the island economy, along with traditional handicrafts and coarse woolen goods. The newest enterprise for the 21st century is the vigorous exploration for potential oil reserves in the seas around the islands. The Faeroe Islands decided not to enter the European Union with Denmark in 1974 and have resisted most development of tourism and potential oil resources. A referendum for independence from Denmark failed in 2001.

## Fayum

FAYUM (also spelled “Faiyum” or “Fayyum”), comes from the Coptic *Phiom* (“sea”), and geographically designates a *muhafazah* (governorate), formerly a *mudiria* (province) of Upper EGYPT, an oasis in north-central Egypt adjacent to the NILE RIVER, with significant paleontological and archaeological interest. Fayum is one of 26 administrative divisions of the Arab Republic of Egypt and is located in a great depression of the Western (Lybian) Desert south-southwest of Cairo. The *muhafazah* has an area of 707 square mi (1,827 square km) and a population of 1,550,000.

Its capital, located in the southeastern quadrant, also called Fayum, was formerly Madinat-el-Fayum (Medina or City of the Fayyum). The settlement dates to the 12th dynasty (1938–1756 B.C.E.) and achieved considerable importance during the Middle Kingdom. The city was called Shedet in pharaonic times, Crocodilopolis in the Ptolemaic era, and Arsinoe during the Roman period; there were substantial Hellenistic, Roman, Coptic, and Mamluk occupations, and it was a major Coptic Christian center until the Arabs arrived in 640 C.E. The capital is a major Sunni Muslim center with a population of 230,000.

Fayum Oasis, situated 149 ft (45 m) below sea level, is 15 mi (25 km) west of the Nile and separated from the river by a gravel ridge bordered on the west by the Western (or Libyan) Desert. It extends about 50 mi (80 km) east-west and 35 mi (56 km) north-south and is connected with the Nile by the Bahr Yusuf, a canalized river. Irrigation canals were originally dug about 1800 B.C.E.

Paleontologist Elwyn Simons and colleagues conducted research on early anthropoids and other vertebrate fossils from the only continuous sequence of fossiliferous continental middle- to late-Eocene and early-Oligocene deposits on the Afro-Arabian landmass. Important fossils include the genera *Propliopithecus*, *Aegyptopithecus*, *Parapithecus*, *Apidium*, *Oligopithecus*, *Catopithecus*, *Proteopithecus*, *Serapia*, *Qatrania*, and *Arsinoea*.

Human presence dates to the Paleolithic and Neolithic eras; Fayum A is the oldest Neolithic culture in Egypt. Pyramids were constructed on the ridge funerary complex, built by Amenhotep III at Hawara. Ancient scholars Herodotus, Strabo, and Pliny describe the temple pyramid’s courtyard. The Roman cemetery north of Hawara yielded the famous and unique Fayum Portraits.

## federation

GEOGRAPHICALLY, a federation (from the Latin *foedus*, meaning “league,” “covenant,” or “alliance”) is a political system created by the voluntary association of distinct political units and formally established by treaty or compact. It is a system of dual sovereignty. Each unit maintains some form of independent administrative power or local identity and sovereignty. At the federal level, sovereignty normally is confined to group or international relations. Thus we have the united, but separate, states of America or the various independent countries of the EUROPEAN UNION, and the distinct provinces of CANADA and AUSTRALIA as well as 20 or more other countries as current examples. The former Soviet Union claimed to be a federation, but none of its parts had the de facto right of secession or of de facto local independence. Today, it is calculated that there are 21 countries that classify themselves as federal. And there are many economic and military associations that assume the same title, such as the United Nations and the NORTH ATLANTIC TREATY ORGANIZATION (NATO).

Any federation faces a continuing dynamic or struggle between separation of power and a need for unity on specific issues—economic, social or military. Regardless of the forces that created their formation, all federations eventually seek increased centralization and a reduction in the power of their individual units. Some scholars have claimed that only centralized federations last. Scholars consider there to be two basic types of modern federal associations: the original function of an alliance of pre-existing political groups or units and the newer use as a form of decentralization. Decentralizing federations occur when an existing centralized state begins to cede some power to local groups or areas—as with indigenous people or tribal groups.

Generally, federations consist of political entities that share proximity and preferably contiguous borders or territory. Their voluntary association is to increase their power. However, there have been maritime federations whose parts were widely separated, for example, the Greek CITY-STATES. These were more economic in motivation.

Regardless, the distinguishing characteristic and *raison d'être* of any federation is an association of distinct groups that have a strong sense of territorial identity. After the motivation of a need to recognize distinct ethnic and regional politics, it is a recognition of common interests and economies of scale, such as economics (trade), mutual military defense, or need of a unified power-grid or transport system that typically is the reason for maintaining a federation in the 21st century.

Modern examples of federations that reflect this range of motives would include the UNITED STATES, AUSTRALIA, SPAIN, INDIA, ARGENTINA, NATO, the EUROPEAN UNION, MALAYSIA, SWITZERLAND, and many countries in Africa and Central Asia.

## Fertile Crescent

THE FERTILE CRESCENT, an area between the Tigris and Euphrates rivers, was called Mesopotamia by the ancient Greeks. This meant “the land between the rivers.” The Fertile Crescent extends from the eastern shore of the MEDITERRANEAN SEA to the PERSIAN GULF and gets its name from its shape. James Breasted, an archeologist from the University of Chicago, first called it the Fertile Crescent.

This region includes present-day ISRAEL, LEBANON, and parts of JORDAN, SYRIA, IRAQ, and southeastern TURKEY. It is believed that civilization first developed in this area, giving rise to the nickname “The Cradle of

Civilization.” Scientists think that agriculture began in this fertile valley around 8000 B.C.E. Here, tribes of nomads, who had formerly been hunters and herders, settled. Barley and wild wheat were abundant. Besides the rivers and the fertile land, the area had four of the five most important species of domestic animals: cows, goats, sheep, and pigs. The other species, the horse, lived nearby.

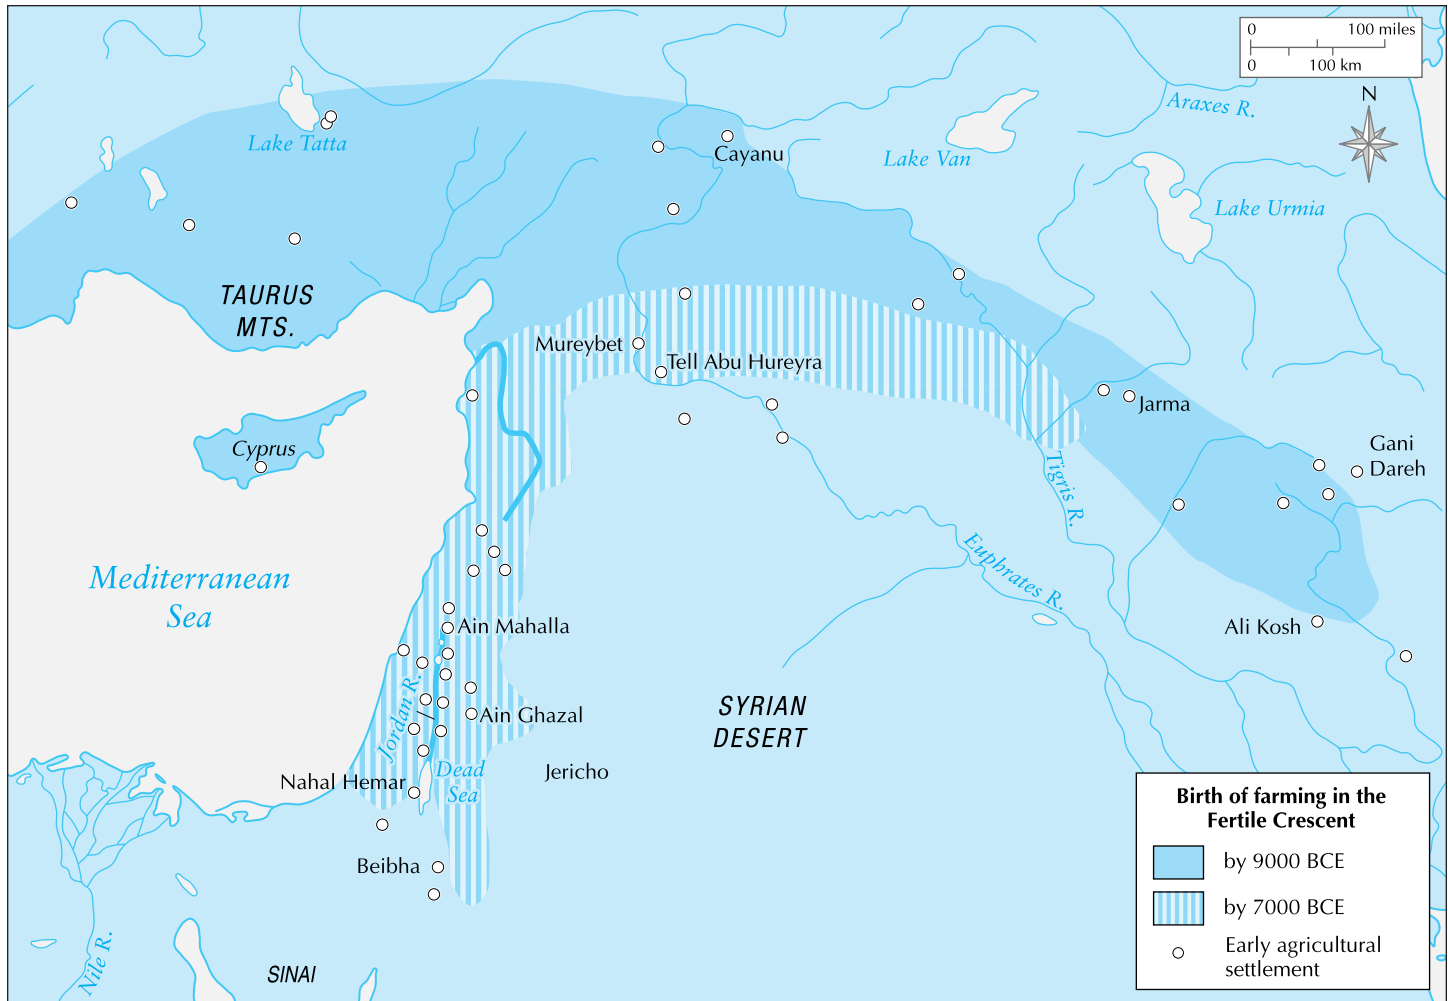

People began to move down from the mountains to the grassy uplands and plains in Mesopotamia. By 7000 B.C.E., farmers were planting wheat and barley and raising domesticated cattle and pigs. The climate of the Fertile Crescent encouraged the evolution of many new species of plants.

Primitive villages stretched across the strip from Assyria to the Euphrates River by 6000 B.C.E. People were learning to cooperate, and social organization grew out of this effort. They learned to irrigate their crops in the drier parts of the Fertile Crescent. By 5000 B.C.E., cities were being constructed in the southern part of the valley. The civilizations of Sumer, Babylon, Assyria, and Persia developed in the Fertile Crescent.

The Sumerians arrived in the Tigris-Euphrates Valley in about 3500 B.C.E. They came from Central Asia and settled in southern Mesopotamia. They took charge of the land and resources there and developed a complex civilization. The region became known as Sumer. Here, city-states developed, each ruled by a king. The king was in charge of construction of buildings and temples, maintaining irrigation systems, overseeing justice, and making trade and defense policies. At first, these kings were elected, but later their positions became hereditary. Because of the number of city-states, there was often tension and conflict among them. Conflicts were often over rights to water or land. Sometimes one city-state tried to conquer another.

The Sumerians invented the first known system of writing. Called cuneiform, it used a triangular-tipped stylus to make wedge-shaped marks in soft clay. The Sumerians also developed the arts of bleaching and dying fabrics and engraving. They developed surveying equipment and built dams and canals. The Sumerian number system influenced our astronomy and our method of timekeeping, with 60 minutes in an hour and 60 seconds in a minute.

In 2000 B.C.E., the Babylonians took control of the Fertile Crescent. One of their contributions was Hammurabi's famous code of laws. They had well-developed literature, religion, history, and science. Their number system was more advanced than the one we use today. From the Babylonians, we received modern

The ancient Fertile Crescent region includes present-day Israel, Lebanon, and parts of Jordan, Syria, Iraq, and southeastern Turkey. It is believed that human civilization first developed in this area.

astronomy and algebra. King Nebuchadnezzar built the Hanging Gardens of Babylon, one of the Seven Wonders of the World. The Babylonian Empire lasted until 538 B.C.E., when the last of the Babylonian rulers surrendered to Cyrus the Great of Persia.

Cyrus was succeeded by his son, Cambyses, who expanded the PERSIAN EMPIRE to include Egypt. After his suicide, Darius I came to power. He instituted a public works program, a postal system, road construction, and a system of minting coins. He also set up a system of weights and measures and built the palace at PERSEPOLIS, the royal center of his empire. It was located in southwestern IRAN.

The Assyrian Empire is hard to pinpoint. The Assyrians, a race of brutal warriors, lived in the northern part of the Fertile Crescent. The first Assyrian Empire lasted only about 50 years before it was assimilated

into the Babylonian Empire in 1760 B.C.E. The Assyrians came to power again in the 14th century and managed to extend their borders. From 1070 to 950 B.C.E., little is known about the history of Assyria, but from 950 to 609, when Assyria was overthrown, its history is well-documented.

The biggest contributions of the Assyrians were in the form of techniques of war and specialized equipment used to carry on war. Also, we still use Assyrian words today for many plants and minerals. Contributions by these early civilizations and others have influenced not only the Fertile Crescent area, but the entire world.

## Fiji

**Map Page** 1128 **Area** 6,767 square mi (18,270 square km) **Population** 868,531 **Capital** Suva **Highest Point** Tomanivi 4,343 ft (1,324 m) **Lowest Point** 0 m **GDP per capita** \$5,600 **Primary Natural Resources** timber, fish, gold, copper, offshore oil.

THE REPUBLIC OF the Fiji Islands, a part of Oceania, is an archipelago in the South PACIFIC OCEAN, about one-third of the way from NEW ZEALAND to HAWAII. The island group consists of 332 islands (110 inhabited) and has a combined area somewhat smaller than NEW JERSEY. The islands consist mainly of volcanic hills and mountains that are lush in tropical vegetation. The climate is tropical maritime and is characterized by a dominance of warm, moist air masses, high levels of precipitation, cyclonic storms (November through January), and minimal seasonal temperature fluctuation.

Fiji has a high birth rate (23/1000 in 2003), a low death rate (5.7/1000 in 2003), a rapid rate of natural increase (1.7 percent), and a notable out-migration. Population density is moderate, life expectancy is fairly high (68.9 years), and the median age, only 23.7 years, is markedly lower than for North America. The majority ethnic group, Fijian (51 percent), is mainly Melanesian with a strong Polynesian influence. Minority groups include Indians (44 percent), who are mostly Hindu, Europeans, and other Pacific Islanders. Christianity is the primary religion among the Fijians and in the island group as a whole (52 percent), especially Methodism and Catholicism, followed by Hinduism (38 percent) and Islam (8 percent). English, the official language, is accompanied by Fijian and Hindustani. Education is free for young people ages 6 to 14, and national literacy is above 90 percent.

Fiji has a well-developed economy based largely on sugar exports, tourism, clothing, copra, gold, silver, lumber, and small cottage industries. Being insular, Fiji

has a long total coastline and adheres to international guidelines for the division of ocean waters. It claims a 12 nautical mi territorial sea and a 200 nautical mi Exclusive Economic Zone for resource development. Given its rugged terrain, only 10.9 percent of this island country is arable. Agriculture employs 17 percent of the official workforce and produces a range of commodities from sugar, cassava (tapioca), rice, and coconuts to sweet potatoes, bananas, pigs, and cattle. With this production, Fiji faces serious ecological issues such as deforestation, soil erosion, chemical contamination, and siltation of internal waters.

Fiji received its independence from the United Kingdom on October 10, 1970, amended its constitution in July 1998 to include national open voting, and today has an elected government. Poverty, subsistence living, political polarization between Fijians and Indians, and national fiscal management remain serious challenges. The country's executive branch consists of a chief of state or president and a head of government or prime minister. The parliament comprises a senate and house of representatives, and the supreme court oversees a legal system borrowed from the British. The country is divided administratively into four divisions, the northern, eastern, western, and central, and one dependency, Rotuma.

CENTRAL MISSOURI STATE UNIVERSITY

## Finland

**Map Page** 1130 **Area** 130,500 square mi (338,000 square km) **Population** 5,190,785 **Capital** Helsinki **Highest Point** 4,426 ft (1,328 m) **Lowest Point** 0 m **GDP per capita** \$30,496 **Primary Natural Resources** timber, metals arable land.

AS CITIZENS OF the northernmost country in Europe, the people of Finland have long experienced the

effects of their nation's absolute and relative location. Finland spans approximately 690 mi (1,104 km) from the 60th parallel in the south to the 70th parallel in the north with approximately one-third of the country falling above of the ARCTIC CIRCLE. While the climate of Finland is moderated by the effects of the Baltic Sea, it is nonetheless greatly determined by its high latitude. The mean annual temperature of its capital, Helsinki, is only 41 degrees F (5.3 degrees C) with an average July temperature of 62 degrees F (17 degrees C) and February temperature of 22 degrees F (-5.7 degrees C).

### PHYSICAL GEOGRAPHY

The physical geography of Finland has also been greatly shaped by its absolute location as a result of continental glaciation that once covered large portions of northern Europe. As the ice advanced and retreated across the landscape, it carved the southeastern portion of Finland into a patchwork of shallow lakes, giving Finland its nickname, Land of a Million Lakes. The movement of ice sheets was never constant, and in their retreat they remained stationary three times, depositing rock and sediment debris to form moraines and drumlins. Stream flow beneath the glaciers deposited additional material, thereby forming ESKERS that stretch from east to west across the country and are called the Salpauselkä ranges. With the retreat of the ice approximately 12,000 years ago, the land itself reemerged from the sea, freed from the immense weight of the glaciers. This process continues today, with the land area of Finland increasing by approximately 2.7 square mi (7 square km) annually.

The postglacial landscape combined with the high latitude provide the basis for a natural environment predominated by boreal forests in the south and low-lying scrub vegetation in the northern reaches of Lapland. As a natural resource, the forests of Finland play a significant role in the economy of the nation with the development of lumber and paper industries. With significant governmental intervention in the 20th century, the Finnish wood industries have worked to increase timber harvests while conserving forested land in the interest of recreation and other nonindustrial uses.

The forests have also been long associated with the development of Finnish culture. Although Finnish society first developed with agriculture, the forests continued to represent a store of wealth for the inhabitants with their abundant flora and fauna. The natural resources of Finland also caught the attention of growing European empires. With the expansions of the Vikings eastward toward RUSSIA, the people of Finland were

eventually incorporated into the Kingdom of SWEDEN and converted from their preexisting pagan beliefs to Roman Catholicism. With the development of the Great Schism and eventual adoption of Orthodox Christianity in Russia, Finland became a religious and imperial battleground between East and West. For approximately 800 years, the majority of contemporary Finland remained within the domain of the Kingdom of Sweden, even converting to Christian Protestantism with the arrival of the Reformation. But after multiple wars and several tenuous periods of peace throughout those centuries, control of Finland was transferred to the Russian empire in 1809.

As an autonomous grand duchy under the control of the Russian czar, Finnish governmental organization remained relatively unchanged and experienced, at least for a brief span of time, an unprecedented period of peace free from the wars that had plagued its people for centuries.

With the demise of the Russian Empire in 1917, Finland sought its own independence and the Republic of Finland was declared. The transition to independence was not without conflict, however, and the people of Finland were embroiled within a civil war between the Reds and the Whites, both of which sought control of the new nation. Less than 20 years later, Finland was once again engaged in conflict, this time caught in the power struggle between GERMANY and the Soviet Union in World War II. The conclusion of the war ultimately resulted in the loss of eastern Finnish territory in the region of Karelia to the Soviet Union.

### WELFARE STATE

Despite the devastation of World War II, throughout the latter half of the 20th century, the democratic government of Finland has invested heavily in both the economy and its citizens, evolving into a Scandinavian welfare state that operates on the premise that the role of government is to care for its citizens from "cradle to grave."

While Finland experienced some economic struggles in more recent decades, its economy has been revived by the growth of high-tech industries within its borders, including companies such as mobile telephone communication giant Nokia. The people of Finland have embraced technology as a globalizing force that allows a country long isolated linguistically and physically to become more integrated into the world economy.

These events, combined with membership in the EUROPEAN UNION in 1995 and the adoption of the euro

as its currency unit in 2002, served to further increase the impact Finland and its people will have upon the rest of the world.

## floodplain

FLOODPLAINS HAVE been a focal point of settlement throughout history and of controversy in recent decades. Humans are drawn to floodplains to cultivate the fertile soils that compose them. Floodplains are some of the best lands for growing crops, but they come with a price. Sometimes, rivers exit their banks and inundate the flat lands and everything on them.

A floodplain is defined as a strip of relatively smooth land bordering a stream that overflows at time of high water. Floods build up the bordering plains with organic-rich sediments. While flooding is sometimes disastrous for humans, it is necessary in the development of floodplains. Rivers create floodplains over thousands of years through two processes, vertical and lateral accretion.

Vertical accretion is the deposition of sediments like sand, silt, and clay from floodwaters. As floodwater spreads out over a flood plain, it slows down and loses energy. As energy is lost, sediments held in suspension drop out and are deposited on the plain. The heaviest sediments, like sand, are the first to be deposited and accumulate near the river channel to form a natural levee. Lighter sediments, like clay, stay in suspension longer and are deposited further away from the river in areas called back marshes.

Lateral accretion is the deposition of sediments to the inside curve of river meanders. As water flows around a curve, the current is fastest on the outside and erodes sediments to create a cut bank. The current on the inside of the curve is of low energy and suspended materials drop out. In this way, point bars are created as the river moves laterally. Because of this, land on one side of the river may be much younger than that of the other.

Today, natural floodplain processes have been largely interrupted in the UNITED STATES. Large networks of artificial levees have been constructed to protect crops and property from flood damage along many of the country's rivers. While flooding is decreased, so is the natural fertilization of soils. Thus, farmers have to apply artificial fertilizers to sustain crop yields, adding to pollution.

The effectiveness of flood control levees is now being questioned. While flooding has been decreased, it is becoming apparent that the severity of floods that do occur is being increased. As more levees are built, less floodplain area is available for rivers to spread over; this means that more water is confined between the levees.

When a levee is breached during times of high water, the result is massive local flooding rather than normal flooding over a broad expanse. Steps are now being taken to curb the flooding problem. Floodplain lands are being purchased and returned to their natural cycles. This effort relieves pressure between the remaining levees and lessens the necessity to continually increase the height of levees.

## floods

OF ALL THE NATURAL hazards in the world, floods are the most widespread. Historically, floods have killed more people and caused more damage than any other type of natural disaster. A flood is defined as an overflowing of water on an area that is normally dry. There are several types of flooding, including river flooding, coastal flooding, urban flooding, inland flooding from hurricanes, and flash flooding. Each has its own causes and characteristics, but all can be deadly and floods can happen anywhere.

Throughout history, people have always built their towns and cities near water, both along the seacoast and along rivers further inland. The water serves many purposes. It is used for drinking, cooking, and bathing. Water in many places has been used as a source of power, to turn wheels that grind grain. Running water is similarly used to create hydroelectric power. Another reason for settling close to water is that it has always been an easy way to travel and to transport goods. The disadvantage of living near water is the possibility of flooding.

The amount of water on Earth is fairly constant all the time. Each day, some of the water on the Earth is lost into the atmosphere through the process of evaporation. Water in rivers, lakes, and oceans is always evaporating at a slow rate. Most water on the Earth is in the form of liquid, but at the poles we find water in its solid or ice form. Water in glaciers is also in the form of ice.

At some places, water is in the form of water vapor in the air. This is the water that has evaporated from the surface of a body of water. A water molecule remains in the atmosphere for approximately 9 or 10 days before it falls as rain or snow. This happens when the amount of water in a cloud becomes heavy enough to form drops of water, which then fall to Earth. Rain that goes into the bodies of water begins the cycle again. Some rain will soak into the ground, where it will spend some time as groundwater.

River flooding is one of the most common types of flooding. It occurs when rainfall throughout the year is unevenly distributed. Too much rain goes into the river at one time and the water exceeds the capacity of the channel. When that happens, the stream will overflow its banks. Another cause of river flooding is melting snow in the spring. In areas with hills or mountains, the snow in the higher elevations melts and the water runs down into the streams. If the snowfall was heavier than usual, floods may occur. Also, spring rains often occur at the same time as the snow is melting, contributing more water to the streams and rivers. The torrential rains that accompany a hurricane or other tropical storm can also cause flooding in rivers.

When heavy rains fall on bare soil, it is churned into mud. This keeps the water from soaking into the ground, and most of it will flow across the surface of the ground, creating gullies leading to rivers and streams.

Coastal flooding occurs when ocean water is driven inland by winds from tropical storms or hurricanes. Sometimes escape routes are blocked by this

high water and people cannot escape. Coastal flooding can also be caused by a tsunami, which is a sea wave sometimes referred to as a tidal wave. These huge waves are caused by volcanic activity or an earthquake.

When urban flooding occurs, the streets in a town become swift rivers and basements fill with water. This is partly due to the fact that land that used to be fields or woodlands has been converted to roads and parking lots. The concrete or asphalt cannot absorb any rainfall and it runs off the surfaces of the parking lots and roads.

### FLASH FLOODS

Flash flooding is flooding that was not expected. Flash floods are the most dangerous of all floods because of the element of surprise. Intense rainfall over a significant period of time can cause flash flooding. The speed with which a flash flood can occur makes it even more dangerous. Flash floods often occur in dry areas where the ground is baked hard. When torrential rains do come, water immediately fills arroyos, or dry stream beds, turning them into raging rivers. The torrent of water rushes through with enough force to wash away sections of concrete road.

Flash flood waters move very quickly and can move boulders, tear out trees, and destroy bridges and buildings. Sometimes a wall of water 10 to 20 ft (3 to 6 m) high carries a huge amount of debris. The worst flash floods are created when a dam or levee breaks and a huge amount of water suddenly pours downstream, destroying everything in its path.

Inland flooding has been the number-one cause of deaths from hurricanes in the past 30 years. In 1999, Hurricane Floyd caused 56 deaths. Fifty of them were people who drowned due to inland flooding. Inland flooding occurs when a slow-moving storm is accompanied by heavy rains. Inland flooding is a threat to communities hundreds of miles from the coast. Over a third of the people who drown during an inland flood are in their cars. Some are trying to escape the flooding, while others are attempting to abandon the cars. Even a foot of water can cause a car to float, and if that water is rushing down a street, the car can be swept away.

All kinds of floods cause problems for people. The worst consequence of floods is loss of lives. Property damage is a major problem with flooding. Houses can be completely demolished or even carried away down a turbulent river. Even houses left standing after a flood usually have substantial water damage and some have structural damage as well. Also, when the water sub-

sides, it leaves behind a thick, sticky coat of mud filled with debris. So even if there is no structural damage, cleaning up after a flood is a big job.

Floods can also spread disease. Water flowing through an area can pick up chemicals and waste products and move them to another place. Most diseases are more easily spread through water than through air. That is one reason it is so important for those in a flooded area to drink only bottled or boiled water.

Besides damaging homes, floods can cause other problems to agricultural areas. Soil can be eroded and crops already in the fields can be ruined. Floods also damage reservoirs and rivers where they deposit the load of soil the water picked up from the fields.

### SEASONAL FLOODING

In some areas, flooding is an annual occurrence and is expected. Seasonal flooding like this took place every summer for thousands of years along the NILE RIVER in EGYPT. The monsoons caused hard rains at the source of the river which filled the river channel to overflowing. This made the land along the banks of the river very fertile in an area of desert. This is one of the few positive results of flooding. In most areas, though, people want to prevent floods from happening. Many solutions have been attempted. In LOS ANGELES and other big cities, concrete channels have been constructed. When there is a lot of rain, the water goes into the channels and is carried out of the city. Here the land can absorb the water that could not be absorbed by the concrete and asphalt ground coverings in the city.

Levees, or large walls, have been built along the edges of rivers to keep them from overflowing. They are high enough so that much more water can flow through the channel. They are fairly effective in the areas in which they are built, but they result in much more water being carried downstream, and this causes problems for areas with no levees. All the water that would have been spread out upstream now floods a larger area than it would have. Also, the sediment that used to be deposited over the whole floodplain builds up in the river bottom, causing the riverbed to rise. Then it can contain less water. Levees can break, too, and when that happens, a flash flood occurs, endangering all who live near the river.

### DAMS AS FLOOD CONTROL

Dams are sometimes used for flood control as well. When they are built near the headwaters of the stream, they can be made to retain heavy runoff, and the water can then be released gradually during dry periods.

*Rescue workers search for survivors and bodies after the Johnstown flood in 1889 in Pennsylvania.*

Floodways are another way of controlling floodwater. This principle diverts floodwaters into a controlled area so that other areas are not flooded. Reforestation can help in areas where flooding occurs because the forests have been cut and the soil eroded.

Preventative measures have also been taken to prevent coastal flooding. These measures have not been as successful as the dams and levees on the rivers have been. Fences and walls are sometimes built where the water meets the land, in an attempt to lessen the power of the waves and keep them from wearing down the beach. However, such structures also interfere with beach formation. Walls and fences often do not work because of the overpowering force of the ocean. In an attempt to prevent flooding on beaches and the resulting erosion and loss of sand, some groups have tried pumping sand from deep waters onto the beaches. This

works for a while, but is expensive. Breakwaters are also built offshore in order to intercept the waves before they hit the beach, but they are an eyesore.

Probably the worst flood in the United States was the Johnstown flood in 1889. Johnstown, PENNSYLVANIA, was a steel town, built on the floodplain at the fork of the Little Conemaugh and Stony Creek rivers. To prevent flooding, a dam had been built 14 mi (22.5 km) up the Little Conemaugh. The South Fork Dam held back a three-mile-long lake on the side of the mountain, 450 ft (137 m) higher than Johnstown. The dam had been poorly maintained. On the afternoon of May 31, after a night of torrential rains, inhabitants heard a “roar like thunder.” Some immediately realized that the dam had broken. Twenty million tons of water rushed down the narrow valley to Johnstown, carrying with it tons of debris from the dam. The wall of water was at times up to 60 ft (18 m) high and leveled everything in its way.

Thousands of people tried to get out of the way of the water, but many were swept downstream with the debris. Some of these people made it downstream to the old Stone Bridge, where the rivers met, by clinging to debris that served as rafts. However, much of the debris caught fire when it hit the bridge. Eighty people who had managed to cling to something as they were swept downstream then died in the fire. Many of the missing were never found, and many bodies could not be identified. The cleanup took years, and bodies were found months after the flood.

Floods on the HUANG (Yellow) River, in CHINA have killed more people than the flooding of any other river in the world. Almost 2 million died in the flood of 1887, and almost twice that many were killed by the flood in 1931. In 1938, there were almost a million casualties. The channel of the river is choked by millions of tons of yellowish mud, which causes the river to overflow often and to change course. In some areas, the river bed is actually higher than the surrounding countryside. Dikes have been built, some as high as 30 ft (9 m) but they don't always hold. For centuries the Chinese have tried to control the river by building levees and dams and digging channels. A huge new dam called the Xiaolangdi Multipurpose Dam was being built in the 2000s. With 10 intake towers, nine flood tunnels, six power tunnels, and an underground powerhouse, the Chinese hope this will finally alleviate their problems with flooding.

As noted earlier, the Nile River floods like clockwork every summer. For many years, the Egyptians took advantage of the flooding. Recently, though, they

have been forced to grow more crops to feed their growing population. In 1970, Egypt built the Aswan High Dam across the Nile 600 mi (965 km) south of Cairo. The dam has stopped the flooding by trapping the water in a reservoir. It is then released during the dry season. This has increased the length of the growing season, as farmers no longer have to wait for the annual floods to recede before planting their crops. However, the land is not as fertile now that the fields aren't flooded annually, so farmers must use large amounts of fertilizer.

The MISSISSIPPI RIVER has regularly flooded its banks for thousands of years. A disastrous flood in 1927 killed 246 people in seven states. It flooded 16,570,627 acres (6,705,894.8 hectares) and caused over \$400 million in damage. This prompted the government to try to tame the river. The U.S. Army Corps of Engineers went to work building the longest system of levees in the world. Today, the Mississippi has 29 locks and dams, and miles of levees, as well as hundreds of runoff channels. Most of the time the system works very well, but in 1993, 80 percent of the private earthen levees on the river failed. Most of the federal levees held, but torrents of water still poured down on fields and towns.

Flooding is more disastrous in less developed countries for several reasons. There is a lack of flood control in most of these countries, and the people don't have an emergency response system in place. Many don't have the technology to put out or receive early warnings. Flooding in the UNITED STATES kills far fewer people today than it did a hundred years ago. Early warning systems are in effect, and meteorologists are much better able to predict floods. Almost everyone has a television set and can learn of an imminent flood in time to take safety measures. Most cities have disaster plans, complete with evacuation routes to be used in case of flooding. Also preventative measures such as levees, dams, runoff channels and breakwaters work reasonably well and make it unlikely that a flood of the magnitude of the Johnstown flood or the 1927 flood on the Mississippi will occur.

## Florida

"THE SUNSHINE State," covering an area of 58,560 square mi (151,714 square km), is the most southern state of the UNITED STATES and is mainly a large low-lying peninsula, measuring from north to south about 430 mi (690 km), bounded by the ATLANTIC OCEAN on the east, the Gulf of Mexico on the west, and the Straits of Florida on the south. The state's northern border is bounded by the states of GEORGIA and ALABAMA. Alabama also bounds the Panhandle's western border. Florida includes the Florida Keys, a chain of islands extending southwesterly from Biscayne Bay at the southern end of the peninsula, and many barrier islands line the coasts. Many of these keys and barrier islands are small and uninhabited. The state's highest point, the Western Highlands of the northern Panhandle, is 345 ft (105 m) above sea level.

Despite popular conception, Florida is a land of geographic diversity. Northeastern Florida is like much of the state, predominantly flatland of hardwood forests and slash pine flatwoods, dotted with the saw palmetto. Riverbanks are lined with mighty live oaks laden with Spanish moss. The northeast's prominent geographic feature is the surprisingly wide and deep St. Johns River, in which dolphins play under bridges.

The Panhandle, with the capital city of Tallahassee and the coastal town of Panama City, is low rolling hills and farmland characteristic of the Deep South. The peninsula, composed of central and south Florida, includes open forests, citrus groves, GRASSLANDS, freshwater swamps, lakes, and open vistas, with tropical hardwood forests or hammocks in the south. The chief city of central Florida is Orlando. Tampa and St. Petersburg, both at the huge Tampa Bay, are the urban center of the Gulf Coast of the peninsula. South Florida's largest city is Miami. The most notable geographic features in the south are the Everglades, a massive area of WETLANDS and perhaps the most endangered ECOSYSTEM in North America, and Lake Okeechobee. The Everglades National Park includes 1.5 million acres (566,580 hectares) and occupies only one-fifth of the Everglades.

Florida's over 1,000 mi (1,600 km) of wide and sandy beaches, such as those at Daytona, Destin, Miami, and Fort Lauderdale are among of the most beautiful and famous in the world. These vary from powdery white sand to crushed shell and coral. Windswept dunes flank many, while other beaches to the south are lined with stately royal palms. The Gulf beaches are known for their warm emerald water in contrast to the thunderous waves of the east coast. The Atlantic seaboard is fringed by 800 km (500 mi) of the Intracoastal Waterway, a long and narrow haven for pleasure craft.

The northern half of the state contains over 320 pristine freshwater springs, recharged by heavy rainfalls. Labyrinths of subterranean rivers connect many of these springs, some opening to the sea. Another curious feature of the northern half of the peninsula is the sinkholes formed from the erosion of the limestone bedrock. These depressions led to the formation of many of the state's over 30,000 lakes and ponds and have often appeared suddenly to swallow cars and homes.

Much of Florida's interior remains wild and undeveloped, and about 50 percent of the state is covered in forest, with about half of that commercial. Its groves produce over 70 percent of the citrus fruits consumed by Americas annually, most notably oranges. The sugarcane, vegetable, cattle, and lumber industries thrive in the state's geography and climate. This diversity of landscape and warm climate, where the temperate zone meets the subtropical, affords an abundance of natural habitats supporting animal life as diverse as the alligator, bobcat, bear, deer, bald eagle, manatee, and the elusive Florida panther.

The state is a major tourist destination thanks to its beaches, good weather, fresh- and saltwater sport fishing, and ever-expanding family attractions extending around the Walt Disney World Resort near Orlando. The usually clear weather also attracted the placement of the Kennedy Space Center at Cape Canaveral; the good weather is punctuated by occasional yet sometimes devastating hurricanes, such as Hurricane Andrew in 1992.

Sparsely populated for most of its history, Florida now struggles with rapid development, urbanization, and population growth, with a population in 2000 of 15,982,378. The state has a colorful and diverse cultural life, ranging from the Deep South atmosphere in the north to the Cuban influence in the south. The few remaining Seminole strive to maintain their culture in the south.

## DISCOVERY AND DEVELOPMENT

Florida has a rich history shaped by its strategic position and geography. It served as Europe's first frontier in North America and a bloody battleground between the Spanish and French empires. The peninsula, although first thought to be an island, was discovered for Spanish exploration and colonization, and corresponding exploitation of its native population, on April 2, 1513, by Juan Ponce de León. It is believed that his landing was near the site of Melbourne Beach on the ATLANTIC OCEAN. Legend says de León sought the fountain of youth, but he was more certainly in search of gold. He named the low expanse of land on the horizon "La Florida" (land of flowers).

Pedro Menéndez de Avilés founded North America's first permanent European settlement, St. Augustine, at Matanzas Bay on Florida's northeastern coast in 1565. Menéndez captured a settlement of French Huguenots at Fort Caroline, at the mouth of the St. Johns River, and later executed the members of a shipwrecked French expedition at the Matanzas Massacre. FRANCE no longer posed a serious challenge. At St. Augustine, a garrisoned town and fort was built to protect the Spanish treasure route, to provide a site for rescuing frequently shipwrecked Spaniards, to serve as a base of coordination for missionary and inland exploration efforts, and maintain Spain's claim to the region. Nevertheless, the St. Augustine settlement was subject to raids by pirates and English privateers, the most famous led by Sir Frances Drake in 1586, in which the town was burned.

In response to pirate and British threats, the construction of a stone fort, Castillo de San Marcos, was started at St. Augustine in 1672. This imposing structure, which still stands, was built from a remarkable sedimentary limestone rock called coquina, which is easily cut when soaked. Coquina is formed from compacted seashells and corals, and was quarried on nearby Anastasia Island. The then state-of-the-art fortress, with its moat, watchtowers, drawbridge, thick walls, and ramparts that swallowed enemy cannonballs without shattering, withstood major pirate and English assaults. From the secure foothold of Florida, Spain's conquistadors led expeditions probing the North American continent, the most famous led by Hernando de Soto.

Except for a period of British rule from 1764 to 1783, during which royal botanist William Bartram recorded Florida's fauna, flora, and native peoples, Florida was a Spanish colony until ceded to the UNITED STATES by a treaty of 1819, with formal transfer in

1821. Statehood was achieved in 1845; thus making Florida the 27th state. The population of the state remained concentrated in the north and the Panhandle until railroad lines were constructed down both coasts, even connecting the Florida Keys, by railroad barons such as Henry Flagler. These lines spurred tourism, development, and periodic real-estate booms.

## footloose industries

THE IDEA OF FOOTLOOSE industries has changed along with the transformation from an industrial to a postindustrial economy. The core concept remains the same, however: A footloose industry does not have a strong locational preference because the resources, production skills, and consumers on which it depends can be found in numerous places. Such a company may therefore be more prone to relocation, hence the term *footloose*.

Footloose industries became prevalent in geographic parlance during the quantitative approach in geography from the 1950s onward. Economic geographers interested in industrial location borrowed ideas and methodology from neo-classical economics. The basic premises of footloose industries are derived from the work of German economist Alfred Weber, who was probably the first to theorize on the location of industries in the beginning of the 20th century.

First, we must assume that the most important factor in industrial location is the cost of transportation (however, this is less and less true over time). Some industries may have a strong resource orientation, that is,

if the raw material used in a production process is heavy and bulky in character, it makes sense to be located close to those natural resources. Heavy manufacturing districts around the world (e.g., the steel industry in northeastern United States) are usually located near major coal deposits. Such a resource-oriented location is often combined with good access to important transportation routes.

Other types of manufacturing can be market-oriented. (Traditionally, the footloose concept has been applied in manufacturing, once the dominant sector in the economy.) Let's take the example of a dairy. If we assume that cows can graze just about anywhere and that milk is a perishable commodity, dairy production should be located close to the consumers the industry serves. For both resource and market orientation, the locational choices of industries are limited, or dressed in more theoretical language, and the so-called spatial margins to profitability are narrow. The opposite is true for a footloose industry. If raw material is easily accessible in numerous locations, markets are dispersed, and the physical properties of the commodity are such that transportation cost makes up a small portion of total cost, the locational choice is much greater.

### INFORMATION FLOW

The locational logic described so far has become less powerful over time for a couple of reasons. Relative transportation costs have declined, which in effect expands the spatial margins to profitability for an increasing number of industries. Moreover, the contemporary postindustrial economy is more and more characterized by flow of information and people rather than bulky goods, which has made traditional transportation cost-based location analysis less relevant. The Internet and other forms of advanced communication technology are said to make location completely detached from both resource and market considerations.

The growth of footloose industries has some strong implications. Cities and regions that once occupied a relatively secure position in the national and global economy because they harbored few industries that could be characterized as footloose are now thrust into an economic environment that is much more insecure. Capital is more mobile where both existing industries relocate and new investment flows to previously bypassed areas. To cope with this reality, local governments increasingly offer incentives to lure footloose industries. Such incentives include tax subsidies, land to build on, and infrastructure accommodations. Not

to be outcompeted by their neighbors, other cities answer with similar measures, which have brought an era of unparalleled interurban competition. As cities are more dependent on the capacity to capture mobile capital, urban policy has inevitably been more business-friendly, and business interests have strengthened their position in urban governance. Cities are even spending significant money to present themselves as good locations for footloose industries by marketing and advertising.

But as cities often offer similar economic incentive packages, location decisions may be determined by other factors. Footloose industries are more likely to locate in places with a perceived high quality of life (i.e., cultural, recreational, climate, educational amenities), where a productive workforce can be attracted. On the other hand, the idea that relocating companies always look for the lowest-cost location has been challenged. For several reasons, industries may not be as footloose as sometimes portrayed. They usually have significant investments in physical infrastructure, they are dependent on local skills and capacities that have been built up over time, and they may share resources and support services with other companies. The high-tech industry is sometimes considered a typical footloose industry because it is neither resource- or market-oriented. However, it tends to cluster for some of the above reasons and thus is not a good example of a contemporary footloose industry.

### GLOBALIZATION

A city's strategy is usually not to attract the most footloose of industries, because they often also produce the lowest-paying jobs. However, the situation is different from a global perspective. With the globalization of the economy, the spatial margins to profitability have widened to encompass large areas of the world. Particularly in industries that are labor intensive, where the products have high value per weight unit, and free trade is the norm, the propensity to frequently seek out new production sites is strong. The clothing industry, for example, is such a footloose industry that has developed a truly global pattern. If companies have the option to outsource much of their production, labor relations are also altered, circumscribing the bargaining position of labor in the United States and other developed nations.

## forests

FORESTS COVER approximately 27 percent of the ice-free surface of the Earth, 13 million square mi or 34 million square km. The world's forests mainly occur in two broad zones: one centered in the tropical regions, the other in the Northern Hemisphere between 32 degrees N and 45 degrees N latitude. Globally, forest composition and distribution are influenced by precipitation and temperature. Soil, landform, and historical factors (for example, glaciation, natural and human disturbance) influence forest structure and composition on a local scale. Forests are generally absent from areas of low or strongly seasonal precipitation, including dry zones at the west side of continents and interior continental regions where annual precipitation is less than .29 in (.75 cm). The 50 degrees F (10 degrees C) isotherm marks the limit of tree growth in the Northern Hemisphere.

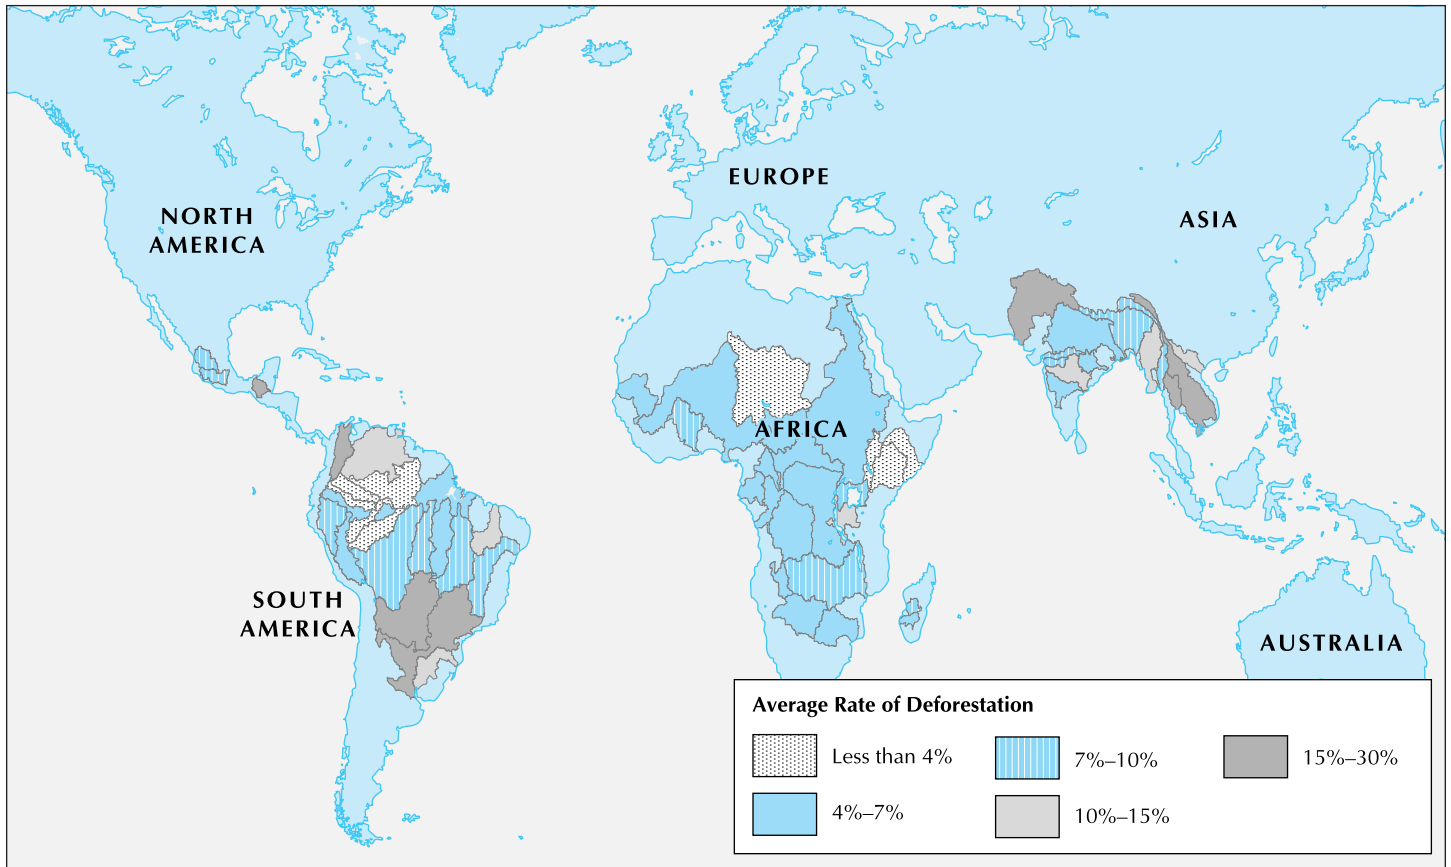

Forests can be classified into major types by LATITUDE, by amount and seasonal distribution of precipitation, or by macroclimate. Three forest types are recognized by latitude: tropical, temperate, and boreal forests. Tropical forests occur in the region bounded by the TROPIC OF CANCER and the TROPIC OF CAPRICORN, where frost is absent and rainfall is abundant but sometimes seasonal. Plants typical of tropical forests, like palms, generally do not occur beyond the 64 degree F (18 degrees C) isotherm. Temperate forests occur at mid-latitudes with warm summers and cool winters. Important temperate forest areas include eastern North America, Central and West Europe, and Northeast Asia. Smaller areas of temperate forest occur in CHILE and ARGENTINA, Southeast AUSTRALIA, and NEW ZEALAND. Boreal forests are restricted to the Northern Hemisphere and generally occur between 50 to 60 degrees N. Extreme winter temperatures, some exceeding -86 degrees F (-30 degrees C), select for cold-tolerant conifer species.

Forests can be further classified by their physical appearance (physiognomy) based on tree architecture

and growth form or by the composition of their dominant species—floristics. Physiognomic classification is often applied at large scales (biomes, ecological regions) while floristic classification is typically applied at local scales. Forests can be grouped based on leaf characteristics into broad-leaved or needle-leaved forest and by leaf phenology (whether leaves are shed seasonally or retained) into deciduous or evergreen forest. Since leaf characteristics are influenced by climate, especially the seasonality of temperature and precipitation, modern classification systems join macroclimatic information and physiognomy to identify forest types.

Two macroclimate domains (groups of ecological regions with similar climate) support forests: the tropical and temperate domains. Tropical domain forest types include tropical and subtropical evergreen broadleaf forest, tropical and subtropical broadleaf deciduous forest, and mangrove forest. Tropical evergreen forests—RAINFORESTS—usually occur between the equator and 10 degrees N latitude, where rainfall is heavy and average annual temperatures approach 80 degrees F (27 degrees C). These forests are multilayered, with numerous vertical vegetation strata, and are composed of species with little cold or drought tolerance. Several types of tropical evergreen forest are recognized including lowland forest (trees greater than 98 ft or 30 m tall, sparse undergrowth, and abundant epiphytes); montane forest (trees less than 98 ft or 30 m tall, an undergrowth of tree ferns, and a rich ground layer of herbs and mosses); and cloud forest (gnarled tree canopy less than 98 ft or 30 m tall, many lianas and epiphytes, and a rich ground layer of mosses, herbs, and ferns). Tropical deciduous forests, in which canopy trees shed their leaves during the dry season, occur where rainfall is seasonal. Mangrove forests grow in tropical and subtropical intertidal zones and are composed of evergreen, salt-tolerant trees less than 98 ft or 30 m tall.

Temperate domain forests include both temperate and boreal elements and are of three types: broad-leaved deciduous forest (leaf fall occurs in autumn and trees are dormant in winter); needle-leaved evergreen forest dominated by conifers; and broad-leaved evergreen forest. Broad-leaved deciduous forest of the northern temperate zone is dominated by oak (*Quercus*), maple (*Acer*), beech (*Fagus*), ash (*Fraxinus*), and lime or basswood (*Tilia*). Broad-leaved deciduous forest of the Southern Hemisphere (Patagonia, AUSTRALIA, Tasmania, and New Zealand) is often dominated by southern beech (*Nothofagus*). Needle-leaved evergreen forest occurs in a broad circumpolar belt in the North-

Deforestation, the sustained removal of trees, is usually a result of human activities, including clearing land for commercial development, cutting wood for house building, making paper, road construction, and clearing of land for growing crops and grazing animals.

ern Hemisphere and in temperate montane areas like North America's Pacific Northwest. Dominant tree species include spruce, fir, and pine. Temperate broad-leaved evergreen forest, the Valdivian and Magellanic rainforests, occurs on the western ANDES' wet slopes. Evergreen southern beeches are common in the canopy; trees may exceed 164 ft or 50 m in height.

Today, virtually all the world's forests are under pressure from a burgeoning human population that consumes land, fuel, and forest products at a rapid rate. Globally, a balance between forest protection and development must be struck to ensure that the ECOSYSTEM services that forests provide will continue to benefit life on Earth.

## fractal geography

IN *THE FRACTAL Geometry of Nature* (1983), Benoit Mandelbrot writes, "Clouds are not spheres,

mountains are not cones, coastlines are not circles, and bark is not smooth.” In an effort to more properly analyze and represent nature mathematically, Mandelbrot developed a new geometric pattern called a fractal. There are various definitions for the complex structure of a fractal, but in general, it is a repeated geometric pattern at progressively smaller scales, which “produce irregular shapes and surfaces.” Mandelbrot outlined four properties of fractals: their dimensions, which are greater than the space they occupy; their “infinitely complex structures”; their quality of “self-similarity”; and finally, he describes a fractal pattern generated by macro iteration.

Mandelbrot’s impetus for creating a new geometrical application for nature’s irregular surfaces stemmed from a theoretical question about measuring coastlines. A coastline, when examined in its entirety from a position above the Earth, may appear nearly straight. Imagine picking a center position on such a coastline and moving closer, like a camera, frame by frame. Within each frame, the perimeter of the coastline changes, revealing more nooks, twists, rough angles, and many other irregularities. Now imagine examining the smallest point of coastline visible with the naked eye—perhaps a centimeter or slightly smaller portion of the coast. Even here, the sand, rock, or other soil formation will produce angles and indentations, which would require measurement to record accurately the length of the coastline. Place that small sample of coastline under a microscope, and it becomes even clearer that although the area of the coastline never changes, the perimeter infinitely changes with each iteration, or repetitious movement, closer to a particular point on the coastline.

This example illustrates the main properties of fractals and why using fractals is a key measuring and modeling tool for geographers. A circle that never changes size or shape can surround a fractal, but when magnifying the fractal, the complexity of perimeters only becomes greater—it is infinitely complex. A fractal retains its complexity no matter how many times it is magnified, and in fact, with each magnification, it technically becomes more accurate. Returning to the coastline example, each magnification reveals the inaccuracy of the first hypothesis that the coastline was relatively straight.

What is important is that because of the infinite nature of fractals and the irregular structure of nature, an element of chaos or randomization can be included into fractal formulas, allowing for an accurate yet approximate measurement.

One quality that many fractals have, which a coastline does not, is “perfect self-similarity.” Computer- and mathematical-generated fractals will often reveal the exact same image at every level of magnification. The perfect self-similar fractal is composed of smaller versions of itself, although there are fractals, including the Mandelbrot Set, that do not create the same image at every iteration, but smaller versions are revealed with close examination. As a natural fractal, there will not be an exact replication of the coastline at every level of magnification; however, the proportions will generally remain the same. Similarly, mountains appear jagged from a distance and remain that way as a person comes closer to them. Clouds viewed from the earth appear to have the same texture as they do from a plane. These natural examples of fractals have qualities of self-similarity, even though they do not represent perfect self-similarity.

Today, geographers often use fractals to model nature’s irregular patterns and structures on a computer, and the beauty of fractals only adds to the increasingly expanding field of fractal geography as more scientists utilize these beautiful mathematical formulas to computer model the phenomena of nature.

## France

**Map Page** 1131 **Area** 212,796 square mi (545,630 square km) **Population** 60,180,529 **Capital** Paris **Highest Point** 15,863 ft (4,807 m) **Lowest Point** -6.6 ft (-2 m) **GDP per capita** \$25,700 **Primary Natural Resources** coal, iron ore, bauxite, zinc, potash, timber.

ONE OF THE DOMINANT nations of Europe since the 9th century, and of the world since the 18th cen-

tury, France is today one of the leaders of the movement toward European unity that will change the balance of the world economy. It is the largest country in western Europe, occupies some of the richest agricultural land, and has a dual orientation—both toward the Atlantic and Mediterranean worlds—that makes it unique among the states of the EUROPEAN UNION (EU).

The French Republic can be divided into Metropolitan France, the historical nation-state in Europe, and its overseas components, known as the DOM/TOMs. The DOMs, or overseas departments, are fully component parts of the republic, and include MARTINIQUE, Guadeloupe, FRENCH GUIANA, and Réunion islands. The TOMs, overseas territories, are not fully incorporated. They include FRENCH POLYNESIA, NEW CALEDONIA, WALLIS AND FUTUNA ISLANDS, and the French Southern and Antarctic Territories. There are also two “territorial collectivities” with special status: Saint-Pierre et Miquelon and Mayotte. These departments and territories are leftovers from the two periods of French colonial expansion: the 18th century in North America and the Caribbean, and the 19th century in Africa. Today, the global French-speaking community, or Francophonie, includes large areas of North and West Africa (ALGERIA, TUNISIA, MALI, and CÔTE D’IVOIRE, for example), and the Canadian province of Quebec. French linguistic and cultural influences remain to a lesser extent in other countries in the MIDDLE EAST (LEBANON and SYRIA) and Southeast Asia (VIETNAM, LAOS, and CAMBODIA).

Metropolitan France is often called “The Hexagon,” due to its roughly six-sided shape: the Atlantic coast, the English Channel, the northern border with BELGIUM, the eastern borders along the RHINE RIVER and the ALPS, the Mediterranean coast, and the PYRENEES MOUNTAINS that divide France from SPAIN. The axis of the hexagon is generally about 600 mi (960 km).

France’s capital, PARIS, is at the center of the northern part of the country, and has dominated French history, culture, and economics since its founding as the royal capital in the 10th century. The population of Paris (about 10.5 million) outnumbers France’s other large cities by 10—one in five French people lives in greater metropolitan Paris—yet regionalism remains strong in many areas: Marseille and Lyon in the southeast vie for the title as France’s second city, while Toulouse and BORDEAUX are rivals for dominance in the southwest. Nantes, Lille, and Strasbourg are regional hubs at the extremities of France’s western, northern, and eastern borders. Nice is also among France’s largest cities, a center for Riviera tourism, but has been

*Mont-Saint-Michel, in the English Channel in northwest France, is accessible by land at low tide and surrounded at high tide.*

part of France’s territory since only the middle of the 19th century.

This late addition of Nice (or Nizza, in Italian) reflects the composite nature of modern France. Known to the ancients as Gaul, named for its Celtic inhabitants, the country takes its modern name from later immigrants, the Germanic Franks, who settled the northern and eastern parts of Gaul after the 4th century, giving their name originally to the area immediately surrounding Paris, today known as the Île-de-France. Other parts of modern France retained their separate identities for centuries: Burgundians in the east, Aquitanians and Gascons (Basques) in the south, Normans and Bretons in the northwest. Loosely unified by the Frankish King Charlemagne and his successors in the 9th and 10th centuries, the French kingdom did not take its familiar modern shape until several centuries

later, with the incorporation of Provence, Burgundy, and Brittany in the 15th century, followed by Flanders and Alsace in the 17th century, and finally Lorraine and Corsica in the 18th century.

Nice and Savoy were the final additions, in 1860. Since the Revolution of 1789, France has become a highly centralized state, and as a result, much of these regionalisms have lost their intensity. The Breton language, for example, has very few native speakers. New mixtures of culture and language are affecting the cultural landscape of France, however, with increasing numbers of immigrants from former French colonies in Southeast Asia and Africa, particularly from North African states such as ALGERIA and MOROCCO.

Today, between 5 and 10 percent of all people living in France are Muslim, affecting the sights and smells of many of France's larger cities, particularly in southern cities like Marseille, where the percentage of Muslims is estimated at nearly 20 percent. At roughly five million, France has the largest Muslim population in Europe. France also has the largest Jewish population in Europe, about 650,000.

Metropolitan France is divided into 96 departments, created during the French Revolution, named for prominent geographical features like rivers or mountains. In 1985, these were regrouped into their older, historic regions, such as Picardie or Aquitaine. Local government continues to exist at both the departmental and regional level, but the regional governments are increasingly pressing for further autonomy from the central government in Paris. Areas with distinct culture are especially interested in greater autonomy, such as Brittany and Alsace, but only Corsica has a significant movement towards outright independence. The 22 regions are as follows:

- Alsace
- Aquitaine
- Auvergne
- Basse-Normandie (Lower Normandy)
- Bourgogne (Burgundy)
- Bretagne (Brittany)
- Centre (consisting of the former provinces of Touraine, Orléanais, and Berry)
- Champagne-Ardenne
- Corse (Corsica)
- Franche-Comté
- Haute-Normandie (Upper Normandy)
- Île-de-France
- Languedoc-Roussillon
- Limousin

- Lorraine
- Midi-Pyrénées (including Toulouse, Armagnac and Foix)
- Nord (the former provinces of Flanders and Artois)
- Pays de la Loire (the former provinces of Anjou and Maine)
- Picardie
- Poitou-Charentes
- Provence-Alpes-Côte d'Azur
- Rhône-Alpes (including Dauphiné, Savoie, and Lyonnais)

Geographically, France can be divided into several regions of highlands divided by broad plains that follow the contours of France's four longest rivers: the Loire, 626 mi (1,010 km); the Seine, 477 mi (770 km); the Garonne, 403 mi (650 km); and the Rhone, 324 mi (522 km) within France. Another major river, the Rhine, forms France's border with GERMANY for 100 mi (161 km). France's plains cover about two-thirds of the total area. Two major basins dominate: the Paris basin in the northwest, drained by the Seine, and the Aquitaine basin in the southwest, drained by the Garonne.

These two rivers are also the main rivers for transportation in France, not the Loire or the Rhone, which are generally too susceptible to flooding and unpredictable currents. Another river, the Adour, drains the basin at the foot of the Pyrenees in France's far southwestern province of Gascony.

Several canals connect France's rivers. The first to be built, the Canal des Deux Mers, was built by Louis XIV in the late 17th century, to connect the Garonne and the MEDITERRANEAN SEA. Today's canal system links all of France's major rivers, and goods can be transported to the Mediterranean from the North Sea via the Meuse, Saône, and Rhone rivers. Some large hydroelectric projects were developed in the 1950s, particularly in the swifter mountain rivers of the south. The most famous of these is the Génissiat dam, on the Rhone above Lyon, which was the second largest in Europe when it was built in 1948.

Today, France is dismantling many of these water projects, in an effort to restore wetlands and natural habitats along its riverbanks. There are few large lakes in France. The largest are formed in low-lying areas along the coast, such as the flat, marshy deltas of the Loire and Rhone rivers. Other parts of the coast vary dramatically, between the chalk cliffs of Normandy, the barren rocky shores of Brittany, and the low-lying

beaches of Languedoc, and the Côte d'Azur, the area of France's famous Riviera. The Riviera encloses the sovereign principality of Monaco, a large percentage of whose residents are French citizens.

France's highest points are along its borders, in the Alps to the southeast and the Pyrenees to the south. The Alpine peak of Mont Blanc, on the border with Italy, is the highest point in Western Europe. Lower peaks are in the Jura and Vosges mountains in the east, plus the Armorican highlands in Brittany. The center of France is dominated by the Massif Central, an ancient weathered PLATEAU with narrow, twisting river valleys. Part of this plateau was once an area of volcanic activity, which left behind the dramatic conic peaks of the Auvergne, such as the Puy de Dôme and the Puy de Sancy. The presence of volcanism is still marked in this area by its mineral water springs, the source of famous bottled water like Volvic. Another area of the plateau further to the east was affected by tectonic activity and the upthrust of the Alps, resulting in the steep ESCARPMENTS of the Cévennes, a region known for its dramatic gorges. The island of Corsica, 115 mi (185 km) to the southeast of the mainland in the Mediterranean, is also mostly mountainous.

The climate in France is mostly continental, with considerable influence from winds and moisture from the Atlantic Ocean. Brittany especially is affected by fogs and rains off the ocean. Higher levels of moisture in the north mean denser vegetation and substantial areas of rich forest land, particularly in the Vosges and Jura mountains, and the valleys of the Aisne and Meuse rivers. The drier south has its share of forests as well, particularly in the flat sandy area of the southwest known as the Landes, which is covered with pine groves. Areas in the southeast have a Mediterranean climate, with seasonal winds blowing across the sea from North Africa, known as the mistral. Higher elevations have a mountain climate, particularly in the southeastern regions of Dauphiné and Savoie. These variations in climate and topography have developed a rich diversity in flora and fauna across the country.

Most of France is still very rural, covered with some of the largest forested and agricultural land in Europe. France produces much of the grains, fruits, and especially wines that are consumed within the EU. In 2003 France produced roughly 20 percent of the total EU agricultural output. France is also a leader in industrial production—machinery, chemicals, automobiles, electronics, and textiles, among others—though France is not as blessed in raw materials as some of its neighbors are. Coal and iron ore were mined for many

*A low-lying beach at Nice, on France's southern coast, has the character of the region's Mediterranean outlook.*

years in the Ardennes region and the Saar basin along the northeast frontier, and they were the source of much of the friction between France and Germany in the 19th and 20th centuries. Franco-German cooperation since the end of World War II has been a cornerstone of the economic integration of Europe, including the introduction of the euro in January 2002. Coal's importance has also largely been replaced because of extensive development of nuclear power.

France is the largest producer of nuclear power in Europe, about half of the EU total, generating 75 percent of France's electricity. Over 1,860 mi (3,000 km) of coastline means that maritime activities have had a central place in the French economy for centuries, but France's tourism industry is today one of the principal contributors to the gross domestic product, catering to over 60 million people a year, the world's most visited

country. Since 1995, France has ranked as the world's fourth strongest economy, with trade surplus continuing to grow, particularly in areas of aerospace, telecommunications, electronics, and software. Companies like Renault and France Télécom have a truly global presence, but French industry is still burdened by an overcentralized bureaucracy. Other products known worldwide include French couture by Dior and Vuitton, fragrances by Chanel and Givenchy, and wines and champagnes from primary areas of French viticulture: Burgundy, Bordeaux, and Champagne.

French history has followed a sequence of tensions and conflicts with its neighbors, first the English, then the Spanish, then the Germans. Political instability has been a norm since the French Revolution overthrew the thousand-year-old Capetian monarchy after 1789. Since then, France has been governed by two restoration monarchies, two empires, five republics, and more than twelve constitutions. Since World War II, however, France has been one of the major engines behind the unification of Europe. The French language continues to be one of the great *lingua francas* of international diplomacy.

## French Guiana

FRENCH GUIANA, or Guyane française, is the only one of the three Guianas (British, Dutch, and French) to retain its political links with Europe. Having been a full part of the French state as an overseas department since 1946—and thus a part of the EUROPEAN UNION—its citizens look to Europe more than to South America for cultural and economic identity. Indeed, the space center at Kourou, the primary launch site for the European Space Agency since 1964, accounts for about one-fourth of the area's entire income. Though physi-

cally a part of the South American continent, for historical, economical, and cultural reasons, French Guiana, along with its neighbors SURINAME and GUYANA, is generally categorized as part of the Caribbean.

French Guiana is the easternmost of the Guianas; it is also the smallest and the most sparsely settled. Its population of nearly 190,000 cluster along 234 mi (378 km) of coastline or along the country's numerous rivers. The longest of these rivers, the Maroni, forms the western border with Suriname. The rivers emanate from a hilly interior that steadily climbs to the heights of the Tumuc Humac Mountains (the easternmost segment of the Guiana Highlands which stretch from here to VENEZUELA). These mountains, along with the river Oyapock, form the border with the Brazilian province of Amapá to the south and east. Further to the southeast lies the vast DELTA of the AMAZON RIVER, about 250 mi (400 km) away. The coast is highly affected by this proximity, and its swamps and coastal lowlands are continually replenished by organic material swept up the coast from the delta by the Guiana Current. Much of the economy of French Guiana depends on the abundant shrimp found in the river estuaries. The interior is still 90 percent forested and unsettled, and though full of valuable hardwoods and gold, it remains largely unexploited because of unmanageable distances and high costs of transport to the coasts for shipping.

The French were the first to settle in the region, in 1604 (even before they settled in CANADA), but the coastal settlements changed hands with the English and Dutch before settling on the present divisions in the early 19th century. Early settlers grew tobacco and cotton and obtained dyes and woods from the indigenous peoples in the interior (members of the Tupi-Guaraní family). French Guiana was not developed as extensively as its British and Dutch counterparts, due to periodic outbreaks of typhus, malaria, and yellow fever. Its swampy lowlands thus gained a reputation as one of the least healthy climates on Earth and attracted few settlers. Instead, the French government turned the area into one of its major sites for penal colonies, including the notorious Devil's Island, just off the coast from Kourou, which was closed in 1945. The last penal settlement was closed in 1951.

The population, mostly a mixture of French settlers, convicts, and ex-slaves, plus a few Indian and Chinese immigrants brought to work in the 19th century, became French citizens in 1848, was fully represented in the legislature from 1877, and became a full overseas department in 1946. Since 1946, there has been population growth from Hmong refugees from

LAOS, and French continentals who have chosen to retire here. The latter form a strong minority group, whose political party, the National Front, continues to oppose any discussion toward independence, owing to the department's heavy dependence on imports of food and energy from France.

## French Polynesia

FRENCH POLYNESIA IS a French overseas territory situated in the south central PACIFIC OCEAN. There are five inhabited archipelagos: the Society, Tuamotu, Gambier, Australes, and Marquesas island chains. The islands are volcanic but the Tuamotu chain is made up of low coral atolls of which there are 80. French Polynesia numbers 121 islands in all, 76 of which are inhabited.

The volcanic islands are mountainous and the interior is generally inaccessible. Only the coastline and low hills are inhabited. These high islands are ringed by coral reefs that enclose shallow lagoons. Tahiti is the largest island and covers 402 square mi (1,041 square km). The capital, Papeete, is on Tahiti and approximately two-thirds of the population live on that island. Temperatures range from 77 to 86 degrees F (25 to 30 degrees C), and the climate is tropical and humid with a relatively dry season that runs from April to October and a rainy period from then on, when temperatures generally rise.

The French Polynesian archipelagos were sighted by European explorers in the late 1500s and early 1600s. But Tahiti was officially "discovered" by the British in 1767 and baptized King George's Island. The Marquesas Islands were annexed by the French in 1791 and the rest of Polynesia became a French protectorate in 1842. In 1880, Tahiti became a colony.

The other South Pacific archipelagos were gradually annexed, and together the islands came to be

known as the Etablissements français de l'Océanie. In 1946, the islands became a territory and acquired relative autonomy. In 1957, the Etablissements were renamed French Polynesia.

French Polynesia has its own government with a president and a territorial assembly that has 49 elected members. The Tahitians elect two deputies to the French National Assembly and one senator to the French Senate in Paris.

The president of the French Republic appoints a high commissioner (*haut commissaire*) who is responsible for public order and safety and ensures that civil liberties are properly respected, but he or she does not exercise executive power, which is in the hands of the territorial government. Autonomy was extended by statute in 1977, 1984, and 2004. FRANCE retains jurisdiction in matters such as foreign affairs, currency, defense, public order, civil liberties, and higher education. The Polynesian government has authority in all other areas. The official languages are French and Tahitian (*reo maohi*).

Nuclear testing was carried out in Polynesia on the atolls of Mururoa and Fangataufa in the Tuamotu chain from 1966 to 1996. The economic windfall was instrumental in the territory's development. In 1996, when testing and the related funding came to an end, the French government made important financial commitments in Polynesia to ensure future economic growth and sustainability. The economy is based on the provision of administrative and commercial services, but French Polynesia does have a relatively healthy fishing industry and produces black pearls. The islands are also popular tourist destinations for the French and other Europeans, making tourism an important part of the local economy.

Nevertheless, government subsidies are essential to French Polynesia's economic survival. The islands import far more (mainly from France) than they export (mainly to France), but JAPAN and AUSTRALIA are also important trading partners.

## French Southern Territories

ONE OF THE MOST remote spots on Earth, the French Southern Territories consists of three groups of islands in the southern INDIAN OCEAN, not too far from the coast of ANTARCTICA, and a thin slice of the Antarctic continent itself, known as Adélie Land. No one lives permanently in these territories, but they are seasonally visited by teams of naturalists and other scientists.

The territory is officially known as the *Terres australes et antarctiques françaises* (TAAF) and has been an overseas territory of France since 1955 (previously administered as a dependency of the Madagascar colony). The island groups consist of two archipelagos, Crozet Islands and Kerguelen Islands, and two volcanic islands, Amsterdam and Saint-Paul.

Kerguelen is formed of about 300 small islands, with a total area of about 2,700 square mi (7,000 square km). The Crozet Islands are smaller in area, with 5 large and 15 smaller islands. Amsterdam covers an area of 23 square mi (60 square km), while nearby Saint-Paul is only about 2.7 square mi (7 square km). All of the islands are volcanic in origin. Adélie Land lies between 136 and 143 degrees E longitude south of the Antarctic Circle and encompasses about 150,000 square mi (389,000 square km), forming a wedge from the South Pole to the sea. The Antarctic Treaty of 1959 declares all of Antarctica to be a neutral zone, but France retains some claims to Adélie Land and maintains a manned research station at Base Dumont d'Urville.

The Kerguelen Islands are located approximately 3,300 mi (5,300 km) southeast of South Africa. The largest island in this archipelago is called Kerguelen, or Desolation Island, mountainous and mostly barren. Its coastlines are heavily indented by deep inlets and fjords. The Kerguelens lie atop the submarine Kerguelen-Gaussberg Ridge, which accounts for the islands' volcanism. Its peaks are volcanoes but are almost entirely covered by glaciers and permanent ice. The climate is among the harshest on the planet, with rain, sleet, or snow almost every day and nearly continuous wind, averaging 68 mi per hour (110 km per hour) year-round, sometimes gusting up to 123 mi per hour (200 km per hour). Kerguelen lies at the Antarctic Convergence, where upwelling cold water from the south mixes with the warmer waters of the Indian Ocean, creating a natural feeding and breeding ground for birds and marine mammals.

Like Kerguelen, the Crozet Islands form the above-water portion of a submarine volcanic plateau, divided

into two groups of islands—l'occidental (western) and l'oriental (eastern)—separated by about 60 mi (100 km). The eastern group includes the largest island, Île de la Possession, on which is located the only permanent scientific camp, Alfred-Faure, set up in 1961. There are no natural ports or airstrips. Since 1938, the Crozets have been a national park. The beaches are black volcanic sand, washed down from the islands' volcanic peaks, the highest being Pic Marion-Dufresne (3,576 ft or 1,090 m). Unlike Kerguelen, these peaks are not covered in ice.

The islands of Amsterdam and Saint-Paul are the most northerly of the group and are thus devoid of snow and ice, even in winter. Amsterdam is surrounded by abrupt cliffs, and is the site of a permanent base, Martin de Viviès, where about 20 scientists winter each year. Saint-Paul is characterized by a spectacular central caldera that has been invaded by the sea, delimited by two natural rock jetties. These islands, of very recent formation in geologic terms (within the last 700,000 years), are astride a volcanic hotspot over the spreading Southeast Indian Ridge. The islands' greater heights (2,907 ft or 881 m maximum) reflect this youthful geologic age, though no volcanic activity has been recorded since the 19th century.

All of the islands of the French Southern Territories have large populations of penguin, albatross, and seals. Early-20th-century introductions of rats, cats, rabbits, pigs and goats have now mostly been eradicated but left their mark on this fragile ECOSYSTEM. France declared the largest Exclusive Economic Zone (EEZ) in the world around the Crozets, Kerguelen, and Amsterdam-Saint-Paul in 1978 to stop overfishing (principally of the Patagonian toothfish). This EEZ is patrolled by the French navy and Greenpeace.

## frontier

AS WITH SO MANY geographic terms, the concept of frontiers is closely linked with other ideas. In practice, frontiers rarely remain the same; changing with time

and technology, and in the process adjusting the world they have affect upon. It has become common to view frontiers in reference to some political or geographical area that lies beyond the more integrated core of a region and into which expansion could take place. Historically, our image of a frontier often reflected a belief that such places were hostile, empty environments and beyond the reach of settlement. But in a more modern sense, it is more accurate to consider it as peripheral to the primary area of settlement and thus still part of the region as a whole. If we start with this basic idea, we see that frontiers have location, area, boundaries, and some hierarchy. We must also recognize that frontiers can be classified by type, typically political or physical, but they can also be considered as conceptual.

Political frontiers tend to be artificial in the sense that they represent expressions of territoriality on the part of sovereign states as they define their boundaries. They are zones of varying width that refer either to the political division between two countries (or political groups) or to the settled and uninhabited parts of a country. As such, they are part of political geography. Such political boundaries come about for several reasons, but usually we think of them as one of five types: pioneer, antecedent, subsequent, superimposed, and relic.

There are also natural frontiers, physical features that stand out as natural boundaries between places. For millennia, a system of natural frontiers served as the basis for dividing all types of space. This was particularly so for regions, states, and nations, which often pretended that geography was the sole determinant of the limits of states, and that mountains and rivers were limits established by nature to determine the question of property between nations. Curiously, there never has been even one single nation that by virtue of the system of natural frontiers has dreamt of restricting its possessions and the limits of its control.

It must be said that natural features (and natural defenses) such as seas, mountains, and rivers can serve very different purposes. There are times when the sea separates nations, and there are times when it unites them. The great Greek historian Horace once called the ocean the great divider of nations. But it is just as easy to see it from the opposite perspective, as the bond of the world. This highlights the fact that over time, barriers perceived to be inaccessible may have a technological basis to their service as a natural barrier. A simple drive is all that is necessary today to cross great mountain ranges or board a plane in Denver and two hours later land in San Diego. In each case we must ask our-

selves where exactly are the natural frontiers? It is the same story for rivers. The rivers running under bridges are no longer seen as separating nations as they were considered in the days of great city-states. Quite the contrary, they unite them, and instead of being obstacles to overcome they are now viewed as community bonds.

Natural frontiers made perfect sense when all forms of transportation were limited to muscle power and the world was a system of land-based nations. But once you add sources other than muscle power to transportation, the usefulness of natural boundaries as markers for the extent of a nation's frontier comes quickly into question. Major changes in technology have usually resulted in major changes in transportation geography. As you redefine space in terms of time, you also redefine it in terms of distance. If you have ever used the phrase "it's a small world" you know that which was far away even 100 years ago, is right next door today.

A frontier today is the opposition and the contrast of peoples. It is not the PYRENEES, which separates FRANCE from SPAIN, as much as it is the difference in manners, habits, and customs between the two areas. Ideas such as this help clarify the fact that conceptual frontiers reflecting the wants and needs of people play an active role in determining how we view both political and physical frontiers. This does not mean that frontiers no longer exist, for they clearly do. But the scale at which we define them has changed on all levels, as well as has our purpose in determining what frontiers are. Things considered to be science fiction by Jules Verne have become reality.

Politically, we have passed from that which was considered empire to kings and emperors to that which is the empire for multinational corporations. Now boundaries in time and space are reflected as inefficiencies in the market; as costs that hinder the degree to which nations develop.

In many respects, the wish to fix boundaries is out of date. In a century where we talk of colonizing other planets and lay plans for ventures to Mars, it is the will of nations that determines frontiers, not nature. Nations make their frontiers; nations themselves create the barriers that exist between themselves and their neighbors. It is also out of this dominance of the land that a new global perspective has grown, for as the power to dominate nature and eliminate frontiers has expanded, so has the understanding that it has not been done without tremendous environmental cost. This unity of environmental consciousness extends far

beyond the traditional politico-geographic realm, where coalitions of states now discuss the consequences of global action.

The rapid elimination of space as the ultimate barrier has given territory and frontiers new meaning. In an increasingly global world economy, frontier lands whose sparse populations once served as ideal buffers against outside invasion must now be made part of the whole. Today, the entire geopolitical model as laid out by Halford J. MACKINDER has been inverted. Now, instead of providing some type of insular space as a means of preserving a nation's status, frontier space is a threat to national unity if not made a convincing and functional part of the national consciousness.

For regions to remain sustainable, they must have some coherent principle, some organizing factor, focal point, or purpose. This relationship has typically taken the form of the core-periphery model, with a central community or economic driving force defining the core and a less well-defined zone or zones of dependency arrayed around the core. As regions mature, frontier areas pass into the domesticated landscape. New communities must now be founded in locations other than those defined by ideal topography. Two hundred years ago, frontiers were seen as vital to stability in the geopolitical world. Today, frontiers are viewed as the biggest obstacles.

## Fulda Gap

LOCATED IN GERMANY, between the cities of Leipzig and Frankfurt, and oriented along the Fulda River, the Fulda Gap is a name given to a mobility corridor oriented on a line that runs from Leipzig toward Frankfurt. It is bounded on the south by the Vogelsberg Hills

and on the north by high ground north of the autobahn (highway) that transects this area. Early in the beginning of the Cold War (1947–89) NORTH AMERICAN TREATY ORGANIZATION (NATO) war planners developed contingency plans for the defense of Western Europe in the event of a Soviet Union-led invasion. They considered the Soviet ground combat doctrine, the mechanized and motorized nature of modern forces, and the compartmentalized terrain of both West and East Germany (Federal Republic of Germany and the German Democratic Republic). Military planners considered the most likely avenue of approach for the main thrust of an invasion would be down a mobility corridor along a general line from Leipzig to Frankfurt and the RHINE RIVER. The hub of this corridor begins in the vicinity of the towns Erfurt and Eisenach and crosses the old border between East and West Germany in the Phillipstal-Rasdorf area. The route would cross the Fulda River and then run west to the gap between the Vogelsberg Hills and the high ground north of the autobahn. The broader corridor that begins at this gap and runs astride the autobahn all the way to Frankfurt and the Rhine was known by U.S. forces charged to defend this area as the Wetterau Corridor.

The first defensible terrain on the western side of the inter-German border was the Fulda River, which would have to be crossed by any invading force. The mobility corridor remains somewhat restricted by the high grounds to the north and south. Once past this gap, the terrain opens up allowing for greater maneuvering, and would give an invading force more opportunity to invade Frankfurt and seize crossing points along the Rhine River.

The European General Defense Plan called for U.S. forces to deploy along a general defense line that could interdict Soviet forces moving into West Germany along routes through geographic areas such as the Fulda Gap. These operations plans described in detail how the U.S. forces would respond to a Soviet-led attack across the inter-German border. The concept was to delay invading forces long enough for reinforcements to arrive from the UNITED STATES. The plans described the defensive positions and actions of each unit and even laid out the nightmare scenario of use of nuclear weapons by ground forces.

The U.S. Army was most familiar with this invasion route, as General George S. Patton's Third Army had come through the Fulda Gap in its drive from the crossing of the Rhine near Frankfurt to Leipzig in April 1945. Armies have passed in both directions along this corridor in many wars, including the Austro-Prussian

War (1866), Napoleonic Wars (1806), Seven Years' War (1756–63), and Thirty Years War (1618–48). It appears that even the marauding Mongols and the imperial Romans used this route for travel and conquest.

With the break up of the Soviet Union and the reunification of Germany, the Fulda Gap has returned to the archives as a military planning concern. As former U.S. Secretary of State Colin Powell said, "I was defending the Fulda Gap as a young lieutenant. Now it is a tourist attraction."

## Gabon

**Map Page** 1115 **Area** 103,347 square mi (267,669 square km) **Population** 1,234,000 **Capital** Libreville **Highest Point** 3,215 ft (980 m) **Lowest Point** 0 m **GDP per capita** \$5,500 **Primary Natural Resources** cocoa, coffee, timber, minerals (gold).

LOCATED ON THE ATLANTIC OCEAN coast in Central Africa, Gabon shares borders with CAMEROON, Republic of the CONGO, and EQUATORIAL GUINEA. Gabon is a unique contrast to what one might think of in a country straddling the equator. Most of the landscape reflects the influence of Gabon's major river, the Ogooue, West Africa's major river between the CONGO and the NIGER rivers. The Ogooue basin dominates the eastern two-thirds of the country. There are two other lesser regions within the Gabon landscape, the Woleu-Ntem River basin in the north and an interesting coastal plain in the west and southwest.

Approaching the country from the sea, one of the distinctive features first noticed is the extensive parkland that appears in the hills just beyond the coast. Rather than mangrove swamps, many places have

broad open grasslands on terraces beyond the coast that are intermixed with larger old growth trees. Beyond the parkland, the land rises in a long arc of highlands that run roughly parallel to the coast and that separate the upper Ogooue basin in the interior from the ATLANTIC OCEAN.

There are also a number of lakes on the coastal plain below Lambarene that collect water for the lower Ogooue River before it empties into the Atlantic. The southern coastal plain is actually an extension of the sand beaches running north from the mouth of the Congo. The northern portion of the coastal plain is separated from the upper Ogooue region by a series of plateaus ranging from 1,000 to 2,000 ft (300 to 600 m) above sea level.

### HIGHLANDS AND PLATEAUS

Between the two coastal plains is the country's major highland region, the Chaillu Massif that rises to an elevation of 3,215 ft (980 m) at Mount Iboundji, Gabon's highest point. In the north, the plateau lands, which reach some 2,500 ft (760 m), begin to merge as one moves to the northeast, until they join the Cristal Mountains. In the southeast is the hot and arid Bateke Plateau at 2,700 ft (820 m).

Gabon has a typical equatorial climate. Rainfall is heavy and varies by location and time of year. The annual average is almost 120 in (305 cm) at Libreville,

the capital, to 150 in (381 cm) on the northwest coast. Most of the rain comes between October and May. Temperatures show little seasonal variation, averaging about 81 degrees F (27 degrees C) each month of the year. Surprisingly, it does not feel as hot as one might expect for a country astride the equator, and nighttime lows are often near 60 degrees F (16 degrees C) in the highlands.

About three-fourths of the country is covered by dense equatorial rainforest. Within this rich ecological zone grows the Gabon mahogany, a hardwood tree that forms the backbone of Gabon's wood industry. The dense forest vegetation supports a wide assortment of animals including gorillas and elephants. Gabon does not have many mineral resources, but those that it has are important. There are large reserves of manganese and significant deposits of high-grade iron ore in the interior. There are also commercial quantities of uranium. Offshore, there are deposits of petroleum and natural gas.

Finally, while Gabon is a rich country by African standards, many Gabonese are not sharing in the wealth. The disparity in the quality of life is encouraging rapid migration from rural to urban areas.

## Gaia

THE IDEA THAT nature is a holistic unity has been constantly existent throughout human history. The major reemergence of the idea took place in the early 20th century in the name of holism. This reappearance of holism became the foundation of the Gaia hypothesis, the most recent recurrence of the ancient belief of the harmonious interconnectedness among natural phenomena on the Earth. Originally stated by the English atmospheric scientist James Lovelock in the 1970s, this hypothesis and related arguments dominated the academy in the second half of the 20th century. Lovelock insisted on the existence of a single planetary ECOSYSTEM in the universe, Gaia.

Gaia includes all organisms: flora, fauna, and their surroundings, such as the land, waters, and atmosphere. Moreover, Gaia functions as a single organism, a self-regulating system that is capable of controlling deviations in climate, correcting chemical imbalances, and recovering from any other environmental damage. According to this hypothesis, the Earth is a living organism. Humans, of course, are part of Gaia, and if we become too harmful to our habitat, the system will automatically act to bring us to extinction. The microbiologist Lynn Margulis supported this hypothesis, and the novelist William Golding endowed the name, Gaia, upon it. This concept is named after the ancient Greek Earth-Mother goddess in respect to her dual characteristics: a maternal figure to nurture beings who adapt to the environment and, in contrast, a harsh destroyer of lives who do not obey her governance. This goddess figure is a metaphor of a process that we call natural selection.

Using the study of ancient myth and spiritual traditions of Plato, Johannes Kepler, and Johann Wolfgang von Goethe regarding the Earth's origin, the nurturing power of Mother Earth is revealed in the general beliefs that the Earth is a self-regulatory organic whole and that humans need to adapt to the ecosystem for survival. Gaia became a very popular idea in environmental determinism, the belief that the physical environment is the dominant force in shaping cultures and that humankind is essentially a passive product of its physical surroundings. This idea eventually developed into ethical issues of stewardship, trusteeship, and importance of sustainable living. In the Gaia hypothesis, humans are not the owners, tenants, or even the passengers of this superorganism. We are simply surviving our species' "allotted span," as Lovelock put it.

The Gaia hypothesis has emerged as the ideas of several cultures from antiquity, but there were no scientific predecessors to prove the accuracy of the theories. Today, Gaia hypothesis is also used among nonscientists to refer to theories of the Earth as a self-regulating organism that inspires humanistic perspectives as well. Some scientists viewed the concept of Gaia difficult to accept as a scientific theory about Earth, and Lovelock's initial hypothesis encountered much antagonism in this respect.

Although Gaia as a concrete concept has its origin in scientific background, it provides a fitting framework to bridge the gap between PHYSICAL and HUMAN GEOGRAPHY as a whole. The core of environmentalism seeks reconciliation of binary divisions, and the concept of Gaia serves as an example of this current in

contemporary geography. However, today, the Gaia hypothesis is well accepted in the studies of the Earth, including geography, and no controversy exists. Therefore, Gaia is the origin of the idea we gained that life and the environment enjoy a two-way relationship.

### THE EARTH AS AN ORGANISM

The idea of a living Earth—the Earth as an organism—is not new but is quite ancient. With the metaphorical association of Gaia with the goddess and Earth Mother, we have lost this understanding only since the advent of objective science that clearly separated the domains of nature and culture. There were some predecessors who advocated the idea of a living Earth even in the scientific period. James Hutton, the Scottish father of geology, was aware of the Earth as a kind of superorganism. Jean-Baptiste Lamarck, French biologist and botanist, proposed a theory of biological evolution with awareness of the all-encompassing power of the Earth.

Goethe suggested that the planet was an organism of the world soul that permeates and gives teleology to the dynamics and metamorphosis of the overall matter. His idea that life on planet Earth is not just a layer over the lifeless ground but makes a dynamic living whole with the planet (as a global organism) influenced the making of the Gaia hypothesis. Alexander von Humboldt, the father of ecology, was the first to take on the study of the relationship between organisms and their environment. And the Russian scientist Vladimir Vernadsky introduced the concept of the BIOSPHERE. He recognized life as “a geological force” and the atmosphere as an extension of life. As a synthesis of these ideas, much truth exists in the Gaia hypothesis.

The idea of Gaia is based on an environmental perception of nature that varies from one culture to another. We must understand that nature itself is a culturally formulated concept that has different meanings to different peoples. There are two major subsets in viewing nature: organic and mechanistic. In the organic view, held by many traditional groups, people are part of nature. Every habitat possesses a soul and is filled with organisms and thus requires respectful treatment.

On the other hand, most Western peoples tend to recognize the mechanistic view of nature. In this perspective, humans are separate from and hold dominion over nature. Along this line, the environment became an integrated system of mechanisms controlled by external forces according to natural laws and understood by the human mind. The Gaia hypothesis is praised for

its questioning the dominant mechanistic view of humans that justifies ultimate human control over nature.

The Gaia hypothesis has a close association with ecofeminism as a part of ecotheology. Although the Judeo-Christian tradition elevated a sky-god to a remote place from the Earth, the harmonious relationships between people and the habitat, sky and the Earth, and male and female should not be disrupted. Emergence of teleology was not avoidable as a result of the disappearance of the Corn Mothers and all other female deities. Thus, the Gaia hypothesis subscribes to this spirit of ecofeminism by revisiting an ancient holiness of ecosystem as a whole.

### BIRTH OF THE GAIA HYPOTHESIS

In the early 1960s, Lovelock collaborated with the National Aeronautics and Space Administration (NASA) to investigate evidence of life on Mars. In an effort to design instruments to detect the presence of life on Mars, the environmental differences between the Earth and Mars led Lovelock to think about what constitutes life, and how it can be detected under varied circumstances. Lovelock hypothesized that the most general characteristic of life was that it takes in energy and discards waste products in return. He also assumed that living organisms would conduct cyclical exchange by using the planet's atmosphere, as organisms on the Earth breathe in oxygen and expel carbon dioxide. According to this hypothesis, life on Mars would also leave a substantial chemical signature on the atmosphere. It could probably be detected from the Earth, so Lovelock thought that it would not even be necessary to send a spaceship. This Mars question inspired Lovelock to concentrate on the Earth and the nature of its atmosphere.

Observing the Earth from a Martian perspective, Lovelock looked back at the historical interaction between Earth organisms and the atmosphere. He noted that bacteria and photosynthetic algae started to remove carbon dioxide from the atmosphere, producing oxygen as a waste product about 3 billion years ago. Over the course of time, this process changed the chemical content of the atmosphere to the level of oxygen poisoning, which was relieved with the advent of organisms powered by aerobic consumption. The atmosphere is supported by the process of cumulative actions of numerous organisms. The holistic effect of these processes was that the Earth itself appeared as a living entity within the universe. Lovelock suggested that the Earth could best be characterized as a superorganism—this is the birth of today's Gaia hypothesis,

which recognizes the Earth as a self-regulating organism. There are at least two versions of the Gaia hypothesis: weak Gaia and strong Gaia. Weak Gaia is the assertion that the Earth's climate and surface environment are actively regulated by animals, plants, and microorganisms. Strong Gaia is the unashamedly teleological idea that the Earth is a superorganism that controls the terrestrial environment to suit its own ends, whatever they might be. On this, all humans and other organisms are mere icing on the Earth. Lovelock seems to favor strong Gaia. He believes that it is useful to regard the Earth not as an inanimate globe of rock, liquid, and gas driven by geological processes, but as a biological superorganism, a single lifeform, a living planetary body that adjusts and regulates the conditions in its surroundings to suit its needs.

### GAIA AND HUMANISM

According to Lovelock, the Earth behaves as if it were a superorganism, which is composed of all the living entities and of their material environment. When he first came up with his Gaia hypothesis, this new idea caused disputes among scholars as much as it impressed people around the world. Gaia has even grown out of scientific research into the realm of humanism in a short period of time. The Gaian perspective of the Earth provides the parameters for species survival by focusing on powerful resilience against any forms of disturbance. There are no special roles assigned to humans in the concept of Gaia.

The thesis is an Earth-centered perspective, and humans have to find their place to adjust within the natural order set by the Earth. Humans must respond in collectivity to unwritten laws of Mother Earth, recognizing themselves as a tiny piece of a puzzle to compose the Earth.

This understanding also delineates several concepts such as deep ecology and transpersonal philosophy. The Earth started out as a self-regulating organism, and humans were supposed to adapt to their environment. After several millennia, however, this power relationship has been transformed in many ways—this is why it is important to consider the interaction between Gaia and humanism today. There are new dimensions to the Gaia hypothesis as humans increase their impact on the Earth. Humanization of the Earth is continuing throughout history, and this fact offers a variety of case studies of our places on the Earth.

Today, with the rise of technology, humans began to obtain more dominant roles within the Gaian circle, shaping the cultural and physical landscapes and im-

pacting habitat through the exploitation of resources. Keeping balance with other organisms, each cultural group has developed its own ways to understand nature and how humans should relate to it.

Western scientists describe Gaia as a large and systematic integration of biophysical and economic phenomena. However, in a simpler and truer term, the reality for most humans is a mosaic of culture-bound worlds, each seeking to negotiate values of social and ecological integrity into eventual global integration. New research possibilities have been opened by this discourse. Gaia hypothesis certainly inspires us to rethink and redirect this scientific society, and reflecting upon the mythological, religious, and aesthetic origins it contains is of vital importance today. It is not a mere nostalgia toward ancient ideals, but exploring Gaia means recognizing the potential to help the world from the ecological crisis we, human beings, have brought on by ourselves.

### CRITICISMS

Lovelock recalled the cold neglect from the professionals to the Gaia hypothesis that lasted until the late 1970s. Then the Gaia hypothesis began to be highly criticized in the late 1970s by many scientists for being teleological, indicating that the hypothesis is based on a belief that all things have a predetermined purpose. Teleology in a Christian sense often emphasizes the embodiment of God's plan on the Earth. Lovelock experienced severe difficulties with many scientists who considered the theory teleological in that it required foresight and planning by biota.

It is in this venue that the Gaia hypothesis inevitably raises the issues of teleology that were revealed by criticisms from scientists: Whether nonhuman beings, such as ecosystems or evolutionary processes, can have a specific "purpose." Lovelock states that his Gaia theory demands responsiveness in the systems, but it does not include awareness, foresight, or intention. The response of organisms is always automatic, and natural selection divides the fate of those that are fitted or not for the conditions. The Gaia hypothesis was very critically received, in particular by the molecular biologists Richard Dawkins and Ford Doolittle. They argued that organisms in this theory would require foresight and planning and could not act in concertation. Scientists Dawkins and Doolittle denied the possibilities of the evolving feedback loops that stabilize the Gaian system.

They argue that as Gaia cannot reproduce itself, it cannot be alive. Gaia was also objected by the clima-

tologist Stephen Schneider and the geochemist H.D. Holland. They also claim that the theory is not scientific enough because it is impossible to test it by controlled experiment. In 1988, Schneider organized a Gaia conference, a meeting of the American Geophysical Union solely to discuss Gaia and its plausibility. This conference terminated teleologism associated with the Gaia hypothesis. Lovelock presented a new version of the Gaia hypothesis from which he abandoned any attempt to argue that Gaia intentionally or consciously maintained the complex balance in its environment that life needed to survive. This new hypothesis was more acceptable for the scientific community. Lovelock supported his new hypothesis with the metaphor of Daisyworld.

Using computer simulations of the Daisyworld parameters and a mathematical approach with evidence, Lovelock proved that the controlled stability of the climate by life and the idea that the Earth as a self-regulatory organism should not be referred to as teleological. The new Gaia hypothesis stated that Gaia was homeostatic, that is, that the biota influence the abiotic world in a way that involves homeostatic feedback, and it convinced Lovelock's contemporaries. During the Gaia conference, James Kirchner, a physicist and philosopher, suggested that there is not one Gaia hypothesis, but several hypotheses. He then described five of these: Influential Gaia, Coevolutionary Gaia, Homeostatic Gaia, Teleological Gaia, and Optimizing Gaia. After initial criticism, the Gaia hypothesis is now considered an essential part of ecological science, proposing the planet as an organism to be the object of both ecological and humanistic studies. Today, most ecologists are confident to characterize the biosphere as a superorganism and consider this hypothesis as relying on the concepts of biosphere and biodiversity. After experiencing the series of struggles, the Gaia hypothesis is a fully recognized entity in ecology in this century.

### GAIAN FUNDAMENTAL ETHICS

In Lovelock's view, humans as one group of organisms are peripheral yet dangerous, along with the technological evolution to the life systems of the planet. Our fundamental human-centered concern is to preserve the Earth as we want it. Lovelock believes that ideas of stewardship of the planet are the reflection of our arrogance. The large plants and animals are synonymous with the icing on the cake; the basis of life—what matters for a living planet—is microbiological matters, over which humans have no control. This raises major questions about responsible behavior and living of in-

dividual humans and social groups. Gaian thinking suggests an alternative to the human-centered view that the world is mechanistic and that everything can be reduced into "parts," which associates life with the laws of physics and chemistry. The new view emphasizes the interconnectedness of the living world as a unitary organism.

According to this perspective, this world is not the world of machine, but the world of organism. Thus, this understanding enhances our awareness that we cannot treat nature as a machine and immerse ourselves in the world as participants. In this way, the Gaian worldview can influence the making of our ethics that bridge humans, ecosystems, and the planet. The Gaian view may make it possible for humans to see themselves as significant (because we are conscious and self-reflexive) parts of a symphonic interaction, which becomes the meeting ground of this scientific theory and humanistic studies. An understanding of Gaia could even become the focus for religious studies, thus influencing a change in human impact on the planetary process. Lovelock explains that Gaia means a religious as well as a scientific concept, and in both spheres it is manageable. Therefore, God and Gaia, theology and science, even physics, biology, and humanities, are not separate, but they create a unitary way of looking at the world.

## gallery (galeria) forests

GALLERY FORESTS are commonly defined as any forest along a river or stream, especially in a grassland. Since geographers frequently cite BRAZIL as the best example of this phenomenon, we often use the Portuguese word *galeria* to identify it. Gallery forests are also found in places other than Brazil. For example, an article in the journal *Landscape Ecology*, discussing gallery forest expansion in KANSAS, quotes the Spanish explorer Francisco Coronado as saying in 1541, "There is not any kind of wood in all these plains, away from the gullies and rivers, which are very few." Gallery forests are common in tropical Africa, too.

Brazil's Amazon basin is covered mostly by tropical RAINFOREST. To the south, many tributaries of the AMAZON RIVER flow northward through tropical savanna GRASSLANDS. Detailed vegetation maps of Brazil show fingerlike extensions of tropical rainforest protruding from the Amazon along the banks of these tributary rivers. These protrusions are called gallery forests. On smaller streams, the crowns of gallery forest trees interlock above the stream. If you were to float down such a stream, you would travel through a long green tunnel or gallery of vegetation.

Tropical rainforests typically exhibit tremendous biological diversity. A small patch may contain many species of trees. These trees are tall and form a leafy canopy 100 ft (30 m) or more above the ground. This canopy prevents much sunlight from reaching the forest floor, which generally has limited amounts of undergrowth. Wherever sunlight does reach the forest floor, however, a profusion of bushy plants known as jungle vegetation is the result. One place where this occurs is along the banks of large rivers. Tropical gallery forests, therefore, contain plenty of jungle vegetation.

Many of the animals that make the gallery forest their home live in the canopy. Arboreal animals are well adapted to life in the trees. South American monkeys, for example, have prehensile tails to help them grasp tree limbs. Birds seek foods such as the seeds in fruits or tree-dwelling insects.

Most trees in Brazil's gallery forests share some common traits. They are mostly hygrophytic (water-loving), well suited to an environment that undergoes prolonged flooding each year. Most are dense hardwoods such as mahogany and teak, prized by lumber merchants for such uses as flooring, cabinetmaking, boatbuilding and interior trim. Exploiting this resource is a challenge, however. First, the trees do not occur in pure stands. Second, once found and cut down, they

are difficult to transport to the sawmill. Because the wood is so dense, the logs will not float. Despite these difficulties, loggers feel that the effort is worthwhile, since a single tree may fetch several thousand dollars.

Loggers are taking even the less desirable trees, converting the wood into charcoal for use in one of Brazil's iron smelters. Gold mining and other mining activities complicate the picture. Not only do mines scar the surface of the Earth, the mercury that the miners use to process the gold pollutes the rivers. Fish take up the poisonous mercury, making them unfit for human consumption.

### CONTROVERSIAL POLICIES

Controversies have developed concerning the best policies for the Brazilian government to implement with respect to the Native Americans living in the forests. Many of these indigenous people, though migratory, prefer to live in villages along the banks of rivers, where they can maximize protein intake through fishing and hunting. Such a location exposes them to exploitation and harm by outsiders. Although the government has implemented safeguards for the natives, federal agencies have limited resources for enforcement. So the natives are faced with a dilemma: retreat deep into the rainforest, where resources may be more scarce, or stay where they are and suffer the possible negative consequences.

Geographic scientists are dismayed to see the steady destruction of Brazil's rainforests and gallery forests. They point to such problems as the disappearance of plants that may have medicinal value, the shrinkage of habitat for animals, the climatic consequences in terms of accelerated global warming and decreased rainfall, soil erosion, and possible job losses because sustainable economic development may no longer be possible. Estimates made from study of the latest satellite images suggest that Brazil's forests may disappear well before the end of the twenty-first century, much sooner than originally predicted.

## Gambia

**Map Page** 1113 **Area** 4,361 square mi (11,300 square km) **Population** 1.36 million **Capital** Banjul **Highest Point** 174 ft (53 m) **Lowest Point** 0 m, **GDP per capita** \$1,700 **Primary Natural Resources** peanuts, millet, sorghum, corn, sesame, cassava.

GAMBIA IS BORDERED by the ATLANTIC OCEAN on the west and surrounded on the remaining three sides by SENEGAL. The smallest country on the continent of Africa, Gambia is composed of a narrow strip never more than 30 mi (48 km) wide. This narrow strip of land borders the banks of the Gambia River for 200 mi (320 km) above its mouth. The river, whose source is in GUINEA and which flows 600 mi (970 km) to the Atlantic, is navigable throughout Gambia and is the main transport artery.

Sand beaches line Gambia's coast, while inland lie swampy river valleys whose fertile alluvial soils support rice cultivation. On higher lands are cultivated peanuts—the country's chief cash crop—and some grains. The climate is warm and fairly dry.

A large number of ethnic groups live in Gambia with a minimum of intertribal friction. The Malinke (Mandinka) is the largest, followed by the Fulani (Fula), Wolof, Diola (Jola), and Soninke (Serahuli). Approximately 3,500 non-Africans live in Gambia, including Europeans and families of Lebanese origin. More than 95 percent of the population is Muslim, while Christians of different denominations account for most of the remainder. English is the official language, but a number of African dialects are spoken in the country.

During the late 17th century and throughout the 18th, FRANCE and England fought continuously for political and commercial supremacy in the regions of the Gambia and Senegal rivers. Great Britain was given control of Gambia by the 1783 Treaty of Versailles. Gambia achieved independence on February 18, 1965, as a constitutional monarchy within the British Commonwealth.

On April 24, 1970, Gambia became a republic following a referendum. Until a military coup in July 1994, Gambia was led by President Sir Dawda Kairaba Jawara, who was reelected five times. In November 1996, the retired Colonel Yahya Jammeh became pres-

ident of the Republic of The Gambia. He was reelected in 2001.

Despite attempts at diversification, Gambia's economy remains overwhelmingly dependent on the export of agricultural products, of which peanut products form the bulk. Other exports include dried and smoked fish, cotton lint, palm kernels, and hides and skins. About three-quarters of the population is employed in agriculture, which accounts for 33 percent of the gross domestic product. Millet, sorghum, rice, corn, cassava, and beans are grown for subsistence. The main industrial activities lie in the processing of agricultural products. The EUROPEAN UNION, CHINA, JAPAN, and Senegal are the country's leading trading partners. Gambia is one of the poorest nations in the world and heavily dependent upon foreign aid.

CLAUDIO O. DELANG  
FRANKLIN COLLEGE, SWITZERLAND

## Ganges River

ORIGINATING IN TIBET and flowing 1,557 mi (2,507 km) from northwest to southeast through INDIA, the Ganges River empties into the BAY OF BENGAL. Known as the Ganga in India, it is the most important river in South Asia, sustaining the lives of literally hundreds of millions of people daily. Along with its sister river the INDUS, the two create the broad and densely populated Indo-Gangetic Plain that stretches in a great arc from the ARABIAN SEA, along the Himalayan foothills to the Bay of Bengal. The divide between the two great river complexes is a mere 300 ft (91 m) in elevation.

The early civilizations that were born on the banks of the Indus moved easily across to the waters and fertile lands of the Ganges. The great literary traditions of oral hymns of the Vedas tell of the conquest and settlement of the Ganges by Aryan-speaking migrants. The

*The Ganges is the most important river in South Asia, sustaining the lives of literally hundreds of millions of people daily.*

Ganges has always been a primal and spiritual force to the millions who have lived along its banks across the millennia of history. Still today, the Ganges is the holiest of rivers in the Hindu tradition, and the faithful flock to it for spiritual cleansing and healing.

The Ganges is a goddess, Ganga devi, one of the two daughters of Meru (the HIMALAYAS). The river is honored in the ancient Vedas and in the two great epic poems, the *Ramayana* and the *Mahabharata*. Even the Lord Vishnu bathed in these holy waters that wash away all sins. Great annual festivals bring massive crowds to sacred sites along the Ganges and especially during the *Melas* that occur every few years on auspicious dates. The waters of the river are considered immaculate, and any amount can purify people, places, and objects.

The Ganges River basin covers almost 25 percent of India's area. The Himalayas bound it to the north and the Vindhya Range in the south. The Ganges has its source from the huge and ancient glaciers of the Himalayas. Fittingly, the three great rivers of South Asia, the Indus, the Brahmaputra, and the Ganges all have their source fairly close together in the Himalayan foothills. The Indus winds down into KASHMIR and on through the Punjab and Sind to the Arabian Sea. The Brahmaputra journeys to the north on a long journey in Tibet only to join the Ganges far downstream in BANGLADESH and strengthen its rush to the sea. In the

northern part of the Ganga River basin, practically all of the tributaries of the Ganga are perennial streams being fed by the snowmelt of the Himalayan Mountains. However, in the southern part of the catchment basin, located in the states of Rajasthan and Madhya Pradesh, many of the tributaries have significant flows only during the monsoon months of June through September. It is during these times the Ganges is most prone to flooding.

The Yamuna, the principle tributary to the Ganga in India, originates less than 100 mi (62 km) east of the source of the Ganges. It flows to the south and almost parallel to the Ganges for most of its 870 mi (1,400 km) course. They join at the holy city of Allahabad, where they are said to converge with the mythic Saraswati River creating a site of pilgrimage for Hindus. Other major rivers that bring the waters of the Himalayas down to the Ganga are the Ghaghara, which joins near Chhapra in Bihar, and the Gandak, which comes in near Patna.

Within the borders of Bangladesh, the Ganges meets the Brahmaputra (called Jamuna in Bangladesh) and greatly increases in volume. Here the Ganges takes on the name Padma as it continues, creating one of the world's largest river deltas. The Padma splits into innumerable watercourses that are known as the Mouths of the Ganges as they spill into the Bay of Bengal.

Pollution by growing population pressure is the river's greatest challenge. Over 380 million humans live within its catchment basin. Little public sanitation exists to deal with the sewage that is generated. Industrial effluents, many toxic, grow in volume with continued economic development.

Water volumes of the Ganges and its many tributaries can drop significantly during the dry period of the annual monsoon cycle. Lands that are flooded in the wet season must be irrigated by tube well during the dry season, as all arable land must be worked to support such a large population.

## gender geography

GENDER GEOGRAPHERS, prominent in the discipline since the 1980s, focus their research on the differences between men and women in virtually all aspects of social, economic, and political life and the resulting inequalities that result. The sub-discipline of gender geography has grown dramatically over the past two decades and there is a specialty group within the Association of American Geographers (AAG), the main professional organization, which has gathered significant numbers of researchers: the Geographic Perspectives on Women specialty group (GROW). This organization is well represented at national and regional AAG meetings and it has its own newsletter and website.

Gender geography has its roots in the compelling women's rights movement of the 1960s and the emergence of feminist theory in the social science disciplines. Gender research examines the ways in which gender inequality has emerged. In particular, the focus in gender geography is on the oppression of women, as evidenced in the differences seen in the attitudes and behaviors of men and women in the traditional settings of home, workplace, and social situations.

The capitalist economic system underwent significant changes in the 1980s. These changes brought about equally significant changes in the traditional relationships that existed between men and women. The workplace began to open up to more women and more women sought and gained political office. Women in middle-management positions began to strive for loftier roles in their organizations. In many cases, they encountered what is called the "glass ceiling," a limit to how high they could rise in the leadership of an enterprise. Prior to the dramatic economic changes seen in the 1980s, women's roles were clearly identified. The work world predominantly found in urban places was the realm of men, while home and a neighborhood or suburb were the places for women. As such, women were marginalized with limited access to opportunities outside the home.

A woman with preschool-age children was even more restricted. In order for her to engage in the workplace, she needed to find adequate day care for her child and ensure that she had an automobile for the trip to and from work. If the family had only one automobile, tradition held that the man would have preference for its use. The male workplace in the city in many cases was in a building that was unsafe for women to approach and enter. Relatively inaccessible entries and

long, unattended corridors put women in a position of perceived danger. The work of gender geographers focused on these situations, brought them to light, and advocated for change.

### A NEW LOOK AT GEOGRAPHY

Gender geography is concerned with the oppression of women and inequalities that are found in their treatment in the economic and political sectors. The approach of gender geography, however, is not to be limited to the development of geographies of women but to bring about changes within the discipline of geography itself and, where necessary, to challenge the existing theory and practice within the discipline and bring them into line with gender findings. Challenges have been made as well to current research practices and methods of teaching that are perceived to reflect a strong masculine bias within geography.

The aim of the gender geographers, then, is to ensure that their perspectives inform all of cultural and human geography. Cartography is a case in point. Research suggests that a strong masculine bias exists in maps and that little mention is made of women in the discipline. There is compelling evidence, it is contended, that the role of women in geography and cartography has been far more extensive than has been reported to date. There is further evidence that abundant information on the status and experiences of women is available on existing maps that have remained relatively unused in geographical research.

### INTERNATIONAL STUDIES

The 1990s brought forth a number of significant studies on the status of women in the world. Some of the most heart-rending outcomes of these studies point to the deplorable social and economic conditions experienced by women in the developing regions of the world. These studies provide an abundance of evidence to support the claims of the gender geographers centering on the oppression of women and the clear dominance of masculine bias. Rates of illiteracy are much higher among women in developing countries, a direct reflection of the generally lower number of years of school attended by women in these regions.

An extreme example of the plight of women was exposed during the recent war in AFGHANISTAN. Under the Taliban regime, women were not allowed to go to school, they could not gain employment, and they were required to wear a burkha, a garment that covered them from head to foot. Other studies have pointed out that far more women are malnourished worldwide

than are men. Ironically, women grow 50 percent of the world's food. In some African countries the figure approaches 80 percent. Perhaps the most telling indicator of male bias is the practice of female infanticide. Many regions of the world have such a strong bias toward having male offspring that female babies may be destroyed in hopes that a subsequent pregnancy will yield a male child. This practice is especially favored in CHINA and INDIA.

In 1979, CHINA instituted a national policy dictating that families have only one child. As expected, female infanticide increased dramatically into the early 1990s, when the Chinese government relaxed this stringent policy. The United Nations International Conference on Population and Development (1994) in Cairo drew attention to the plight of women worldwide. Policies were instituted that aimed at giving women more control over their own lives through the achievement of economic equality and opportunity, a greater voice in reproductive decisions, and increased access to education. These policies marked a departure from previous pronouncements, which were limited to the implementation of population control measures.

In September 1995, the Fourth World Conference on Women was held in Beijing. A strong declaration of women's rights and equality marked this event. Topics addressed included sexuality and childbearing, violence against women, discrimination against women, and the assurance of women's equal access to opportunities in the economic system. Specifically, these included access to land ownership, availability of financial credit, vocational training, information, and communications.

### UNITED NATIONS MEASURES

The United Nations (UN) set of Human Development Indicators (2003) contain two compilations directly applicable to gender geography. These are the UN Gender-related Development Index (GDI) and the UN Gender Empowerment Measure (GEM). The GDI is a composite index measuring achievement in three basic dimensions: a long and happy life, knowledge, and standard of living. The actual measure of these goals is gained from data on life expectancy at birth, adult literacy rate, and estimated earned income.

Gender differences are greatest in the developing world. Estimated earned income strongly favors males, even in the developed countries, in some cases, double that of women. With few exceptions in the developing countries, adult male literacy rates are significantly higher than that of women. The only category that favors women is life expectancy. Throughout the world,

women on average tend to outlive men. The GEM measures gender inequity using three basic dimensions of empowerment: economic participation and decision making, political participation and decision making, and power over economic resources. In all three dimensions throughout the world, women significantly lag behind men.

In the category of seats in government held by women (as percent of total), the highest figure is 45.3 percent in Sweden. The remainder of the developed countries report percentages ranging from 10 to the mid-30s. As would be expected, percentages in this category in the developing countries are much lower. The percentages of women occupying professional and technical positions (as percent of total) are more equitable. In fact, some countries (ICELAND, UNITED STATES, CANADA, DENMARK, NEW ZEALAND, and ISRAEL) have more women than men in these categories. Surprisingly, a number of developing countries also have more women than men in these roles (NAMIBIA, MOLDOVA, HONDURAS, and BOTSWANA).

However, the category of earned income is decidedly in favor of men. AUSTRALIA, FINLAND, and LATVIA have the highest ratios of female to male earned income: 0.70. All other countries in the world are below that figure, with some as low as 0.30. Clearly, earned income is a category worldwide that strongly favors men. The GEM ranked only 70 of the world's countries mainly because sufficient data either was not available or was not submitted.

Some of the GEM data have been transformed to map form. The map of managers and administrative positions shows the highest percentages of women in North America, AUSTRALIA, New Zealand, SOUTH AFRICA, and several European countries. The lowest percentages are in the MIDDLE EAST, over half of the African countries, and the Indian subcontinent. It is clear that women remain a distinct minority in the exercise of economic power and decision making. It would appear likely as well that the goal of equality for all people in the world would not be realized soon.

## geographic database

A GEOGRAPHIC database can be defined as a catalog that stores data that are spatially referenced. These databases are collections of similar data that are related either through location, data structure or type, or common underlying purpose.

Geographic databases can be divided into two main data concepts, graphic and nongraphic. Nongraphic data is data that does not “describe” or “define” graphic images or map features. There are four types of nongraphic data: attributes, geographically referenced data, spatial relationships, and geographic indexes. Generally, nongraphic data attributes describe particular map features or are linked to graphic elements through identifiers or geocodes. An example of an identifier or geocodes would be used to describe items or actions at a geographic location such as building permits, accident reports, or tax records. Nongraphic data within a geographic database can take the form of a geographic index or be used to describe a spatial relationship.

Examples of geographic indexes include street addresses, mailing addresses, parcel numbers, or account numbers. Spatial relationship examples include various topological relationships such as connectivity, adjacency, and proximity. All of these elements of nongraphic geographic data are stored in geographic databases as alphanumeric characters.

Graphic data in geographic databases consists of points, lines, polygons, and other map or cartographic features such as projections, coordinate systems, and cartographic symbols. Graphic data is commonly stored in the database in the form of coordinates, symbols, rules, or pixels. There are two methods in which graphic data can be stored within a geographic database: vector or raster. Vector data are denoted by coordinates (example, x and y or latitude and longitude) of nodes and lines or rules for connecting the various lines

into areas. Vector data defines objects, polygons, and other involved units so that they can be displayed or analyzed based upon their associated attributes. Raster data sets are stored as a set of uniform grid cells that represent a continuous surface.

There are many different forms that data models or bases can take. Some of the more basic and widely used ones are hierarchical, sequential, and relational. Hierarchical data models can take the form of parent-child relationships or one-to-many relationships where, for the database to be successful, direct linkages between entries are necessary. Relational data models consist of relational tables where rows are records, columns define the attribute relation, and each cell has a particular attribute value.

Management of geographic databases is very important to help ensure the accuracy of the data, the integrity of the database, and the reliability of the analysis done using a particular database. Included in this management of the database is establishing data standards, definitions, quality, and maintenance schedules. Administrators of digital geographic databases are also charged with controlling access and use of the database, backing up the database and creating and maintaining a data directory or dictionary. The data directory, also referred to as metadata, is essential to the management of a geographic database. Information included in a data directory is the definition of the particular entities, attributes and valid values. Data directories also describe the various entities and attributes when necessary, along with describing the accuracy, completeness, or other data characteristics that are important the integrity of the database.

## geographic information system

GEOGRAPHIC INFORMATION systems are widely known by their abbreviation, GIS. The most popular definition of GIS is: a computer-assisted system for the acquisition, storage, analysis, and display of geographic data. Conceptually, GIS has been defined as

the digital representation of the landscape of a place (a site, a region, a planet), structured to support analysis.

A functional GIS necessarily incorporates software capable of handling geometry, attributes, and topology. Geometry consists of points, lines, and areas that represent places and geographic features located within those places.

Two distinctly different data structures are employed, and each system must be capable of converting or integrating the other. Raster data structures consist of regular grids of intersecting lines that form rectangular cells. In raster GIS, points are represented as individual cells, lines as chains of cells, and areas as patches of cells. Raster GIS is well suited, for instance, to represent satellite imagery collected by electronic scanners or survey samples collected in regular arrays by field investigators.

Vector data structures consist of individual points plus complex geometric structures comprised of points (typically called nodes) and line segments connected by vectors. Vectors are not restricted to right angles. Point features are expressed in latitude, longitude, and elevation or some other coordinate system convertible to such Earth coordinates. They may include, for instance, the corners of land ownership parcels and the intersections of transportation lines. Line features are expressed as points (usually called nodes) connected by line segments. They may include, for instance, road center lines, flight lines, and trajectories of all sorts. Area features are expressed as points and chains of line segments that close to produce polygons. They may include, for instance, administrative areas, ownership parcels, and bounded areas such as fields or forests.

In raster and vector GIS, attributes describe the characteristics of geographic features. Physical attributes may include, for instance, material (e.g., rock, soil, water, ice), temperature, and color. Cultural attributes may include, for instance, religion, language, and ownership.

Topology (not to be confused with topography) represents angular relationships (order, adjacency, etc.) that remain constant regardless of map distortion. Topology is essential if geographic data from different sources, scales, and projections are to be combined in a single geographic analysis.

A commercial GIS primarily consists of software for handling these functions. While some GIS vendors provide sample data or even real geographic data for broad regional coverage, it is generally expected that purchasers will use the GIS software to develop databases tailored to their own locale and analytical needs.

In Western society, people are constantly confronted with practical examples of GIS, but many do not know the term or recognize its many forms. Examples of GIS and its products include automobile navigation systems, geographic profiling in criminal investigations, tax assessment systems, digital weather maps, and even the U.S. military's precision weapons employed in the war in Iraq.

GIS products are overwhelmingly beneficial to society, but certain applications raise serious concerns about privacy and control. Some products currently on the market are advertised for "human tracking" and undoubtedly will be used to monitor and control the locations of individuals. Some applications will be ethical, others will not.

The science behind GIS is geography. On most university campuses, the principal GIS courses are offered in geography departments. The development of GIS, however, has involved a much larger community of spatially oriented disciplines (e.g., cartographers, topologists, and landscape architects), domain scientists (e.g., geologists, foresters, and ecologists), and computer scientists. Broadly, these developers and practitioners refer to their field as geographic information science, often distinguished as GISci.

Geography has been practiced for at least 2,500 years, starting with the ancient Greeks, and it has always been inhibited by the enormous volumes of data required to represent landscapes and regions. GIS enables a new form of automated geography that is revolutionizing society's capacity for understanding and managing just about everything for which location matters, including everything, human or otherwise, that moves or flows.

## geomorphology

GEOMORPHOLOGY IS the study of landforms. Landforms are surface expressions of rocks, as are various features made by rivers, groundwater, waves and currents, winds, glaciers, and corals. Landforms come in all shapes and sizes. A DELTA, PLATEAU, VOLCANO, sinkhole, and beach are all landforms. Geomorphologists are geologists and physical geographers who specialize in the study of landforms.

Geomorphology has two general goals: 1) to explain how landforms vary from place to place; and 2) to develop theories about the origin and development of landforms. In order to achieve these goals, geomorphologists examine the nature of surface rocks and geologic processes, such as soil formation, weathering and EROSION, mass movements, and transportation and deposition of sediments. They use a wide range of techniques for data collection, including field, laboratory, and numerical techniques. Geomorphologic research aids in understanding the role that landform development plays in complex ecosystems. The findings also help prepare for and lessen impacts of hazardous geological events, such as landslides, FLOODS, beach erosion, and slope erosion. The following paragraphs summarize how geologic structure, PLATE TECTONICS, gradational processes, and time influence landform development. The four factors are interrelated so that their combined effects create an amazing variety of beautiful landforms for us to enjoy. The article concludes with a summary of how geomorphic theory in the United States evolved from a long tradition of geological and geographical research.

### GEOLOGIC STRUCTURE

Landforms vary, in part, because of geologic structure. Geologic structure refers to the types and arrangement of materials that make up landforms. The materials are extremely diverse, ranging from sediments, such as finely textured clay deposits on a glacial lakebed, to massive large-grained rock that has crystallized from subsurface magma. There are three basic types of rock—igneous, sedimentary, and metamorphic—but each type has a wide variety of examples that differ according to their chemistry, texture, color, hardness, and so on. Common examples of sedimentary rocks are conglomerate, sandstone, siltstone, shale, and limestone.

Igneous rocks form when liquid magma (molten rock) cools and hardens. In the hardening, minerals take on their shape, or crystallize. There are two basic

subcategories of igneous rocks—intrusive and extrusive. When the magma cools within Earth's crust, the rocks are of the intrusive igneous type. Granite is the most common rock of this type. When magma erupts onto Earth's surface, it cools outside the crust to become an extrusive igneous rock, or lava. Basalt is the most common type of lava.

Metamorphic rock forms when intense pressure and heat cause previously formed rocks (including other metamorphic rock) to deform or metamorphose. (*Metamorphose* in Latin means “to change form.”) Different rocks have their own metamorphic counterparts. Sedimentary rocks, such as limestone and dolostone, change to marble. Low-grade shale becomes sheets of slate, and sandstone turns to quartzite. Metamorphism may occur in igneous rocks as well. Granite recrystallizes to become banded gneiss (pronounced “nice”). Intense heat and pressure can also turn several kinds of sedimentary rocks or their metamorphic products into gneiss. *Schist* is a general term for a group of metamorphic rocks that forms under the most intense pressure and heat.

Earth materials exhibit even more variation in their arrangement. Joints divide rocks and internal forces (compression, tension, and shear) break them along faults, thrust them vast distances horizontally, or deform them by heat and pressure. Rocks may or may not be in layers. Sandstone has layers, but granite is a massive rock devoid of them. Layers of sedimentary rocks may be horizontal, tilted, or folded. Rocks also differ in the degree to which they yield to weathering and erosion processes. Hard rocks and soft rocks wear down to differing degrees. Ridges and peaks occur where hard rocks resist the work of weathering, rain, and streams. Valleys that separate the ridges are where rocks are weak. The rocks in valleys weather easily and streams wash their sediments away quickly.

The arrangement of most sediment varies according to a transporting agent (stream, wind, waves, or glacier). For example, meltwater discharging from a retreating glacier deposits stratified (water-sorted) layers of clay, silt, sand and gravel, but it also leaves behind piles of unstratified (unsorted) debris, ranging from clay to boulder-size materials. Like glacial meltwater, other transporting agents stratify or sort their deposits. Rivers form FLOODPLAINS and deltas; waves leave behind beaches and spits; and winds deposit sand dunes and loess (silt deposits). In contrast, layers of sediment left by corals and groundwater are in situ deposits (the sediments remain at their point of origin). Corals leave behind their skeletons to form limestone reefs, and

groundwater forms various types of calcified deposits, such as stalagmites and stalactites.

## PLATE TECTONICS

Geomorphologists have a big-picture view of the origin and general distribution of landforms through the study of plate tectonics. Plate tectonics refers to the movement and interaction of plates, which are sections of Earth's lithosphere (outer rock layer). Plate movements explain the origin and present distribution of expansive plains, plateaus, volcanoes, and mountain systems, as well as continents and ocean basins. Plates move slowly—generally less than 10 in (4 cm) per year. Nevertheless, their incremental movement over millions of years moves continents and opens and closes vast oceans. Driven by Earth's internal heat energy, tectonic plates have collided and separated several times to create and arrange rocks.

Since the 1960s, geomorphologists have become increasingly knowledgeable about how tectonic plates move and interact. They now understand that mountain-building activities (earthquakes, folding, faulting, and volcanism) occur more often at the edges of plates, where they come together, move apart, or slide past each other. The word *tectonic* is an apt name for these landform-building plates. In the Greek language, *tec-tonic* means “builder.” The most imposing mountain systems of today—HIMALAYAS, ALPS, and ANDES—are on the boundaries of converging plates. The mountains are primarily a result of folding. Volcanism and faulting, although they can have catastrophic results in folded mountainous areas, are of secondary importance to uplift caused by folding along convergent boundaries.

Volcanism plays a key role in building mountains from the seafloor. Where plates are converging beneath the sea, volcanic island arcs, such as JAPAN, the PHILIPPINES, and the Kuril and Aleutian islands, are forming. Where tectonic plates are moving apart on the seafloor, volcanism and faulting are building the world's largest mountain system—the mid-ocean ridge. Additionally, volcanism also forms volcanic islands where a plate passes over a magma plume that is in a stationary location in the mantle, which lies just below the moving lithosphere. The Hawaiian Islands are a classic example. Where plates slide past one another, strike-slip faulting and earthquakes are the dominant tectonic activities, such as in CALIFORNIA, where the San Andreas Fault Zone is so active.

Continental SHIELDS occur away from the edges of plates, where the Earth's surface has been subject to lit-

tle or no tectonic activity. Shields are landscapes of low plateaus and hills. They are composed of ancient rocks that have escaped the destructive forces of plate movement. There are two types of shields—covered and exposed. Covered shields are under a cover of younger sedimentary layers. These strata accumulated at times when the shields subsided and shallow seas inundated the land. Rock-forming sediments from the land (clay, sand, and gravel) and from dead marine organisms covered the shields. Covered shields underlie portions of all of the continents.

For example, sedimentary rocks bury a shield in North America that lies between the Rockies and the Appalachian Highlands. Exposed shields occur where ancient continental rocks lie bare. An example of an exposed shield is the CANADIAN SHIELD of North America. Exposed shields also exist in Scandinavia (lowland SWEDEN and FINLAND), South America (Brazilian and Guiana highlands), Africa, AUSTRALIA, and INDIA.

## GRADATIONAL PROCESSES

The wearing down of elevated areas also influences the nature of landforms from place to place. Relentless erosion by rivers and glaciers has worn down massive mountain ranges, leaving behind only bits and pieces of ancient bedrock. For example, plates collided to arrange rocks of the Appalachian Highlands in eastern North America, as well as highlands in the British Isles, southern GERMANY, CZECH REPUBLIC, and Scandinavia. These areas are actually the roots of mountains that were in the past as magnificent as the Rockies and Himalayas are today. The thickness and age of river-borne sediments that surround the base of these low mountains bear witness to great heights of former summits.

Gradation begins with physical and chemical weathering of rocks and other earth materials. Mass wasting (mass movement) transfers the weathered material downslope. Mass wasting processes include, creep, rock fall, solifluction, mudflows, earth flows, avalanches, and landslides. These processes result from the downslope pull of gravity. Gravity also pulls surface water and glacial ice downslope as they pick up and transport rock fragments produced by weathering. In addition to gravity, solar radiation is an energy source for gradation. It drives atmospheric circulation, which generates storms that produce major erosion agents—rain, meltwater from snow and ice, wind, and ocean waves. Kinetic energy of the erosion agents physically detaches, transports, and deposits sediments to form a variety of depositional landforms: streams de-

posit sediment to form ALLUVIAL FANS, floodplains and deltas; winds deposit sand dunes and loess; waves and currents form beaches; and retreating glaciers leave behind end moraines and outwash plains.

Weathering, mass movement, and erosion transfer sediments from elevated mountains and plateaus to low-lying sedimentary basins. Sedimentary deposits cover vast areas of continental lowlands, coastal plains, and submerged continental margins. Examples of sedimentary basins in North America are the U.S. Central Lowlands region—which includes the interior lowlands of OHIO, INDIANA, ILLINOIS, and IOWA; the Mississippi delta; and the Gulf Coastal Plain as well as the continental shelf beneath the Gulf of Mexico.

### THE STUDY OF TIME

Landforms of the same type differ in appearance because they are in different states of change. Geomorphologists study change in landforms in terms of response times and restoration times. Change in a sandy beach is an example. The time a beach takes to adjust to erosion brought about by a storm's wave energy is its response time. The time required for restoration of the beach to its former shape is its restoration time.

At any given moment, a beach's shape reflects a balance between inputs and outputs of energy (waves) and mass (sand). Storm waves create a negative sediment budget by taking away large amounts of sand. Beaches respond to storm waves by becoming steeper and narrower, but they rebuild quickly after the storm subsides, when smaller waves bring in surplus sand. Such adjustments establish a new equilibrium between the landform (beach) and the process (wave action) affecting it.

The rates of response and restoration among landform types are wide-ranging. A beach typically responds to storms and restores itself in a matter of days, weeks or months, depending on the strength and frequency of storms.

In cases where restoration times are very long, the land may have "leftover" relicts of processes that are no longer active. For example, tectonic or climatic processes that cause the sea level to change may have ended tens of thousands or even hundreds of thousands of years ago. Consequently, coastal areas have relict forms of old shorelines, such as marine terraces and beach ridges. Relict landforms may require a million years or more of gradation by other processes for their removal. Removal of such relicts may never occur, as a resumption of tectonic activity and glaciations

tend to interrupt restoration intervals of these magnitudes.

### THEORIES OF LANDFORM EVOLUTION

U.S. geomorphology experienced spectacular growth from about 1890 to about 1950. American academics recognized W.M. DAVIS (1850–1934) as the leading specialist in the field during this period. Davis developed the technique of "explanatory description" of landscapes. He discouraged experimentation in processes of landscape evolution, because he felt the processes were too complex and landform types too varied. His methodology focused instead on describing three controlling factors of landscape change—structure, process, and time. Davis devised one of the earliest models of landscape evolution—the geographical cycle.

The model posited that landscapes evolve through a sequential series of stages; each stage possesses an indicative set of landforms. Purely descriptive in origin, the observer was supposed to use the model to determine the stage of development of a particular landscape. Followers of Davis conducted few experimental studies on processes, for his descriptive system was deceptively adequate. Intuitive reasoning outpaced investigational proof during these early years.

World War II introduced improvements in aerial photography and new kinds of geomorphologic analysis. Accurate quantitative interpretation of beaches and coasts using aerial photographs were vital to military strategy during the war. Beach studies carried over after the war and led the trend in quantification and experimental verification. A concern for streams, the main suppliers of sand to beaches, was a logical extension of shoreline studies. Thus, the dynamics of weathering rates, stream erosion, and slope development quickly became a major focus of the new approach.

By the late 1960s, quantitative models had all but supplanted Davisian-type descriptive models. In subsequent decades, the role of climate in the genesis of landforms received more interest. Additionally, new technologies involving the study of the ocean floor validated the unifying theory of plate tectonics. Theoretical geomorphology in the United States has used the systems theory approach and has focused on developing quantitative models that replicate and predict geological processes. Geographic information systems, remote sensing, global positioning systems, and isotope dating have accelerated this trend.

## geopolitics

GEOPOLITICS IS POLITICS taking place in regard to geographical circumstances, territorial relations and aspirations of political entities. It derives from the spatial settings of place as well as from territoriality as a universal dimension of human (and animal) behavior. While the spectrum of geopolitical action is very wide, it is never just derived from "geographic imperatives." There are always underlying motivations, constructions and lines of thinking behind geopolitics, whether we speak of geopolitical theories or geopolitical action. In order to understand the relational and proportional settings of contemporary geopolitics, it helps to construct some kind of picture of the asymmetric "geopolitical ideologies" that influence the motives and ideas behind the geopolitical activities of various states and other political actors.

At the same time, geopolitics should not be confused with the field of POLITICAL GEOGRAPHY. Both disciplines have in common the search and identification of an area of study that concerns the connection and mutual interaction between geography and politics. Political geography deals with the study of the existing relations between spatial facts and the political processes, and therefore constitutes the spatial analysis of political phenomena. It concerns the spatial attributes of the political process or can be seen as the study of existing relations between spatial facts and political processes. Geopolitics, on the other hand, is an approach to international politics that insists on the significance of geographic territory and its resources. It represents the study of the geographic distribution of power among the states of the international system,

paying particular attention to the rivalries of the major powers. From a slightly different point of view, geopolitics could be seen as an expression of the foreign policies of states, where those policies are determined by the state's location, natural resources, and physical determinants. Thus, geopolitics and geopolitical analysis constitute the study of international politics seen from a spatial or geocentric perspective. Where political geography deals with the interaction of geographical factors and politics, the interactions of political power and space, geopolitics tries to provide a geographic interpretation of these events by studying the geographical aspects of political phenomena.

## BACKGROUND

A Swedish political scientist, Rudolf Kjellen, originally coined the term *geopolitics* in 1899. Kjellen viewed the state as a living organism and, in developing his ideas, saw geopolitics as the study of the state as a geographic organism whose spatial phenomena could be a land, a territory, a space, or a country. Kjellen believed that in order for a state to be strong, its government had to put in practice five complementary types of policies in order to be successful in its natural expansion. For Kjellen, the aim of the discipline was to demonstrate the role of the geographic characteristics in the conception of the state and the practice of statecraft to the statesman and decision maker.

According to Friedrich Ratzel, the state is a territorial entity with two essential coordinates: the space (*raum*), which he viewed as the total surface or aerial extent of territory, and the position (*lage*), which he referred to as the situation of the territory in relation to other states. Ratzel was also interested in two other ideas: the concept of space itself, namely the sense and meaning of space, and what he called vital space.

There is one definition of geopolitics that seems to be particularly well expressed. In the words of Osmo Tuomi, the geopolitics that emerged in the last decades of the 20th century is by no means comparable to the old framework and theoretical points of view, namely the eternal confrontation between sea power and land power developed during the late 19th century and the first half of the 20th. For Tuomi, theoretical geopolitics studies the relation between physical space and international politics, develops models for the spatial division of the world into cooperating and competing parts for historical, economic and political reasons, and analyzes how the participants interpret the political, economic, and military consequences of this division. The geopolitics of a state or other territorially defined soci-

ety relates to its pursuit of geographically dimensioned aims that are connected with its economic and political position, security and culture.

With the end of World War II, new perspectives emerged for the study of geopolitics and political geography. The international system in the postwar period changed dramatically the notion of the balance of power and introduced strategic bipolarity and nuclear deterrence, concepts responsible for the ideological, political, cultural, and geographic confrontation between the two superpowers and the respective spheres of influence and blocks of allies. It was during this period that geopolitical theory cut drastically with the international situation that had prevailed up to that time, and the realities of the world situation were constantly assisting the development of new weapons, strategies, and techniques for conducting war.

The resurgence of both political geography and geopolitics began in the late 1960s and early 1970s as they ceased to be mere instruments in service of the military establishment/sphere and started to be objects of analysis by academics and researchers who wanted to construct critical reasoning and discourses with respect to the disciplines in question. The renaissance has been particularly manifest after the end of the 1980s, compared with the exclusion and distancing that it suffered after 1945 and for approximately three decades thereafter.

As one legitimate area of study, geopolitics and political geography deal with complicated if not problematic issues like GLOBALIZATION, deterritorialization through constant flows of information and finance, and transnational phenomena that transcend the boundaries of states and seem somehow to erode the concept of sovereignty itself.

In some respects, we live in a world that is becoming boundless, without physical and territorial borders, that bases itself on an increasing, more frequent, and perceptible interdependence among players. In this sense, some authors speak about the end of geopolitics because of profound impacts created by economic globalization. Information technologies and communication are progressively forming and reforming domestic politics and the foreign relations of states, raising doubts about the existence of borders, boundaries, territorial demarcations, and sovereignty itself.

Another major change in the study of geopolitics and geopolitical analysis started in the late 1980s and continued throughout the 1990s: Critical geopolitics. This line of study demonstrates that geopolitical issues and themes can be found in popular culture, movies, or

mass media, that is, the press, TV and radio. These same issues are therefore seen as important forms of popular geopolitics. In comparison to formal geopolitics, the insight of critical geopolitics tries to determine in what manner and to what extent geographic labels do not imply some strong causal relation between physical geography and the behavior of the state and its political structures.

For some theorists, critical geopolitics takes issue with the traditional theories of political geography and opposing positions of geopolitical theories by analyzing their discourses and their role in spatial formation and development. In order to achieve an alternative form of geopolitics, one that intends to serve as the equilibrium in the hegemonic balance, the critical approach offers an examination of the suppositions that sustain particular geopolitical constructions, that is, production and use of geographic knowledge in various orders of power and space. In doing so, critical geopolitics tries to uncover the hidden geographical assumptions in foreign policy decisions and actions.

Following the fall of the Berlin Wall and the demise of the old Soviet system in 1991, a new phase in the international system of states began to take form, thus paving the way for the end of communism as a socio-economic doctrine and a new orientation in foreign policy. The revival of geopolitics and political geography after years of relative neglect has highlighted primary concerns such as the role of geographical scale in establishing political identities. New threats to world security emerged, like regional conflicts, violent nationalism, religious fundamentalism, and sharp inequality between the rich north and the underdeveloped south.

Some authors believe we live now in a more unpredictable and unsafe world. The disintegration of the Soviet empire has created a vacuum on the huge land-mass that was Mackinder's HEARTLAND. And that heartland was also the region that in the past was the heart of the country with which the United States was struggling for global primacy. Geopolitics has once again gained special attention from Russian scholars and policy makers.

And once again, the concept of the heartland is retaining its credibility among Russian authors. Here is demonstrated the high interest in geopolitics, where the Eurasian theory provides a simple definition of the belief that RUSSIA is a unique power and does not need to Westernize in order to "obtain" and reach modernity. At the same time, the orthodox version of geopolitics means the Eurasian heartland is, in geographical terms, the milestone for the formation of an anti-Western

movement, whose aim once again is to ultimately expel the “Atlantic” influence from Eurasia.

Today, geopolitics is a concept built on a plurality of issues within the theoretical framework of international relations and its study. In a widely interdependent and rapidly transforming world characterized by extremes in complexity, geopolitical perspectives can be very useful in defining the international system. This is particularly so with regard to the extent to which geopolitics is able to provide useful explanations of, as well as point out barriers and obstacles to, stable geospatial relations.

In this sense, geopolitics should be taken seriously, for it constitutes in itself a social element and a technological reasoning that helps in the construction of our images of the world. According to John Agnew, this imagination has provided meaning and rationalization to the practice of geopolitics to the extent that it has defined the ideological space from which the geographic categories upon which the world is organized and work are derived.

Geopolitics and political geography then simultaneously justify and legitimate a confrontation like in the days of the Cold War or give a picture of the inequalities that characterize the present (and past) world economy with regard to the representations of a world without limits, borders and boundaries. In the present state of the world, frontiers and borders seem to vanish because of the changes around the notion and function of territoriality. This points as well to the processes of *globalization*, a term highly used (and abused), but also a sometimes ill-defined one that can confuse all forms of economic, political, and cultural theories. The functions of the border and the sovereignty of the state are rendered less important and are therefore reduced to a more irrelevant perspective.

## HISTORIC FOUNDATIONS

In a sense, geopolitics attempts to explain why some countries have power and other countries do not. This basic focus is clearly not new to the modern world. For as long as there have been human societies, there have been groups with power and control and those without. In many regards, this social psychological view of human spatial behavior can be seen as a history written in the language of territory and territoriality, both of which are natural expressions of humans as biological forms.

The special connection between the spatial qualities of countries and international relations has been observed since the Greeks. The Greek geographer and

philosopher Strabo believed that geography was destiny, and that the presence of a given set of geographical circumstances automatically led to some form of political order.

The ancients were true ecologists, for they assumed a strong organic relationship between environment and society. In his book *The Politics*, Aristotle remarked on the impact of climate on human character and, ultimately, politics by indicating that it requires no stretch of logic to see geography and topography as both antecedent to and resultant of climate. But not everyone agreed. Writing in the 16th century, Jean Bodin took exception to the Aristotelian belief in the dominance of geography, arguing that reason, as exercised by statesmen, could overcome the tyranny of geography. Not long after, however, Napoleon Bonaparte returned to the original view, with a bold belief that the politics of a state is its geography.

The formal link between geography and political science that we drawn upon today began a little more than 100 years ago, when the idea of geography being destiny received new emphasis and a name (geopolitics) from Rudolph Kjellen, a Swedish political geographer. Under the general influence of the Age of Reason and a belief that science could be applied to benefit human society, Kjellen sought a science of international politics grounded in empirical bedrock. And for Kjellen, what better bedrock could be found than geography? In short, Kjellen's motivation was bound up with the contemporary conviction that serious inquiry needed to be linked to science rather than to the traditional conception of the humanities.

In 1890 Alfred Thayer Mahan wrote *The Influence of Sea Power upon History*, spelling out the necessity of sea power in facilitating trade and peaceful commerce. Mahan, therefore, believed that the country that could control the seas possessed the greatest power in the world. Thus, the development of a strong navy was an essential ingredient to a powerful state in addition to the country's location. Geographically, this meant that the country with the most power would be the one whose relative location was accessible and connected to other areas via a long coastline and good harbors. Mahan also saw the expression of this power as belonging north of the Suez and PANAMA CANALS.

The late 19th century was a period where the social sciences began to embrace the notions first identified by Charles Darwin when he wrote *Origin of Species*. This evolutionary approach took hold in many schools throughout Europe, particularly in Germany, which believed in a kind of social Darwinism as a working ex-

planation for the evolutionary development of the states of the world, European countries (GERMANY) being the ultimate expression of the theory. The Germans became instrumental in developing this new idea into the field of geopolitics (*geopolitik*) and modern statecraft. In 1897, German natural scientist Friedrich Ratzel developed his “organic theory,” contending that the state is like an organism that is attached to the Earth and that it competes with other states in order to survive. Further, like all living organisms, the state needs living space or *Lebensraum* in German.

Also in the late 19th century, Sir Halford MACKINDER proposed what has become the most widely discussed concept of geopolitics. Mackinder was interested in political motion, observing that the spatial distribution of strategic opportunities in the world was unequal. In his 1904 book *Democratic Ideals and Reality*, Mackinder developed his thesis with a disregard for Mahan’s theory, suggesting that advances in technology were forcing a reevaluation of both spatial concepts and military strategies. As an example, he indicated that with the development of railroads, countries no longer needed to depend on the navy to move large armies. Accordingly, Mackinder believed that the focus of warfare would shift from the sea to the interior portions of countries and continents; something he called the HINTERLAND.

Mackinder then developed the idea of a “pivot area,” located in the northern and interior parts of the Eurasian continent where the rivers flow to the Arctic or empty into salt seas. This area would be pivotal, he believed, as it would be easy to defend and hard to conquer. In later works, he began to refer to the pivot area as the “heartland,” and devised his famous Heartland Theory. According to this theory, Mackinder believed that “He who controls the Heartland controls the World Island (Eurasia and Africa) and he who controls the World Island, controls the world.”

Another German, Karl Haushofer, was a leading proponent of Mackinder’s Heartland Theory and developed a theory around the idea of pan regions. Haushofer divided the world into three pan regions, blocs of power, based on the complementarity between North and South. His ideas represent an early conceptualization of the CORE AND PERIPHERY concept, where a northern core would be connected to a southern periphery. The three pan regions were Anglo-America with Latin America as the periphery; Europe (which he saw as controlled by Germany) with Africa and INDIA as peripheral areas; and JAPAN and its periphery, Southeast Asia. After World War I Rudolf Hess heard

Haushofer’s lectures and later introduced him to Adolf Hitler, who ignored the subtleties of Haushofer’s teachings and used these geographic theories to advance the Nazi cause.

After World War II the study of geopolitics fell into disrepute because of its association with Nazi Germany and the fact that geopolitical theory ascribed a single cause to the success or failure of a country and that did not take into consideration human choice. This was known as determinism, later to be more fully developed as environmental determinism with geographic factors as the foundation for “environment.”

Nicholas Spykman was a proponent of this environmental determinism approach, integrating economic, political, and military points of view into the theory. According to Spykman, states with locations north of the equator would always be more important than those south of the equator. Spykman also disagreed with Mackinder’s Heartland Theory, believing that both sea and land power were important. In advancing his ideas, he believed that the real potential of Eurasia was in the “inner crescent,” a region that included Western Europe, the MIDDLE EAST, South Asia, Southeast Asia, and the Far East. He called this region the Rimland, suggesting that its importance lay in the fact that the region had access both to the sea and to the interior regions. Spykman extended Mackinder’s reasoning on the importance of the Heartland by stating: “Who controls the Rimland rules Eurasia; who rules Eurasia controls the destiny of the world.”

During the Cold War years, policy makers relied on the Rimland Theory as justification for the policy of CONTAINMENT, that is, at stopping the spread of communism. Unfortunately, this led the geopolitics movement in America to take on highly simplified and distorted views whose primary purpose was to serve political ends. Geography was somehow pushed out of the geopolitical equation during this period, when it like economics and other social sciences, began to seek more refined scientific status through mathematics and the development of regional science. Practicing geopoliticians were now chosen from such fields as international relations and history, sometimes even from the military, but not from geography. Geography meant distance, size, shape, and physical features that were all static. The idea of geography as spatial patterns and relations that reflect dynamic physical and human processes was absent.

In an extension of conceptual ideas first developed by Mahan for sea power and later by Mackinder with reference to railroads, A.P. de Seversky, writing in *Vic-*

*tory through Air Power*, believed that the development of air power made land battles obsolete. His contention was that whoever controls the skies would control the world. At the time of his writing, the United States and the Soviet Union were the two most important air powers. He used an azimuthal equidistant projection centered on the North Pole to show the air dominance of the two countries. He went on to indicate that there was an area of intersection visible on the map that he called the “area of decision,” and that whoever controlled this area would be the dominant geopolitical power in the world.

### WALLERSTEIN'S WORLD SYSTEM

During the 1970s, Immanuel Wallerstein developed a world system theory of geopolitics, where the world system was a social system having boundaries, structures, member groups, rules of legitimization, and coherence.

According to Wallerstein, there were two varieties of this so-called world system. One could be viewed as comprised of a world empire where there is a single political system over most of the area. In the other form, there could be several subsystems within the world system, but no single political system existing equally throughout the overall space.

Wallerstein used economics as the cohesive factor in his world system theory and saw the world economy as the base upon which the world system was built; something he believed took original form in Europe during the 16th century and was made possible by a division of labor that was both functional and geographical. Within this world system Wallerstein identified three geographic areas: core states, peripheral states, and semiperipheral states. The advanced countries of the world economy represented core states. They all were believed to have strong state structures, national cultures, and highly integrated populations.

Within the model, trade, technology, and finance connected the economic powers as core states whereby they were also exploiters of the periphery. Peripheral states were weak and typically either colonial states or states with relatively low degrees of autonomy. The third region was comprised of semi-peripheral areas, those places that act as a buffer between the core and the periphery. As a reflection of determinism, Wallerstein believed that the world-system was already fully developed by the 1950s. As such, no country would be able to enter the system and successfully compete, and those countries currently in the periphery would probably never be able to catch up.

The spatial patterns geographers see in the world today are difficult to conceive of as being containable within national boundaries. The world has become an interdependent system where the nation-state is part of a shared area. One of the proponents of this theory is Saul Cohen, who wrote *Geography and Politics in a World Divided*. Cohen divided the world into geostrategic regions, one Maritime Realm, which is dependent on trade and has an external focus, and a Eurasian Continental Realm, which is continental in composition with an interior focus. Within each realm there is a further subdivision into first-order states (the ones that are the most powerful). According to Cohen, Japan, the United States and the European Community represent the current first order states within the Maritime Realm, while CHINA and the Soviet Union are the first-order states within the Continental Realm. Cohen's model also included what he called shatter belt states, which separate the realms or serve to separate regions within the realms.

There were also a group of independent states such as PAKISTAN, INDIA, THAILAND, and VIETNAM, and gateway states that acted as linkages between realms and regions. And finally, Cohen identified states that are asymmetrical. That is, states that are in a region but behave quite differently from the others in the same region.

### MACKINDER'S CONTRIBUTION

Geopolitics analyzes politics, history and social science with reference to geography. Although U.S. diplomat Robert Strausz-Hup's popularized use of the term (for English audiences), the discipline gained most of its attention through the work of Sir Halford Mackinder and his formulation of the Heartland Theory. In January 1904, he introduced his paper “The Geographical Pivot of History” to the Royal Geographical Society. The paper initiated the onset of a new geopolitical era: a method of political analysis, which stressed the importance of geographic factors in determining national interests and international relations.

He questioned traditional perceptions, suggesting that, in the long run, land power was superior to sea power, and he revised the prevailing Eurocentric view of history. During his lecture, he asked his London audience to “look upon Europe and European history as subordinate to Asia and Asiatic history, for European civilization is, in a very real sense, the outcome of secular struggle against Asiatic invasion.”

This theory involved concepts directly opposed to those of Mahan about the significance of navies in

world conflict. The Heartland Theory hypothesized the possibility that a huge empire might to be brought into existence that did not need to use coastal or transoceanic transport to supply its military industrial complex.

If this were so, then such an empire could not be defeated by all of the rest of the world together if they joined against it. The basic notions behind Mackinder's theory involved a change in thinking where the geography of the Earth was being re-divided into a new variation of the notion of the "old world" (most of the Eastern Hemisphere) and the "new world" (the Western Hemisphere and Oceania). The difference was that the archipelagoes that were traditionally able to defend themselves using naval power, Great Britain and, prospectively, Japan, were taken from the old world (the world island), where they had been major players, and added along with the PHILIPPINES, INDONESIA, SRI LANKA, and MADAGASCAR to another part of the world now renamed the "periphery."

The other world islands, AUSTRALIA and NEW ZEALAND, were already part of the "new world" as a result of their relatively short histories and extreme distances from the heartland. Not only was the periphery noticeably smaller than the world island, it necessarily required a great deal of sea transport to function on a technological level equal to that of the world island, given a lack of sufficient natural resources for a developed economy.

### INDUSTRIAL BASTION

Also, the industrial centers of the periphery were necessarily located in widely separated locations, making it rather easy for the world island to send its navy to destroy each one of them in turn, with little chance of a united resistance. The world island could also locate its industries in regions further inland than the periphery, thus providing a well-stocked industrial bastion. This region Mackinder termed the *heartland*. It was essentially comprised of UKRAINE, western Russia, and what today we call Central Asia. Most important in all of this was the fact that the heartland contained the grain reserves of Ukraine, as well as many other natural resources. It could feed and sustain itself for long periods without outside support.

Mackinder's theory outlined a move away from Europe as the pivotal center of history. Instead, it was becoming eclipsed by a new geographical pivot of history, that of the Eurasian heartland. The main advantage of this imaginary center of a world empire, enlarged by the African continent, or world island, was

that it would be invulnerable to direct attack by sea power. Mackinder said that the fate of the world depended on control of the heartland. He suggested that the heartland would be controlled by Russia or a Russian-German combination, shifting the power center from western to eastern Eurasia. However, if Japan and China were to join allegiances, then the centrifugal force in the balance of power might be transferred to Asia alone. One of the more interesting features of Mackinder's theory was his recognition that one did not have to reside in the heartland's pivotal area to control it.

### FUTURE POWER CENTERS

The crossing of cultures and traditions both between Western Europe and Eastern Europe and Europe and Asia marked, for Mackinder, a region of potential strategic importance in determining the power centers of the future. It could be argued that Mackinder's theory was too one-sided. He concentrated on the Eurasian heartland, whereas an opposite heartland could also exist, for example, in America. This could help explain the confrontation of capitalism and communism: the opposite polar being America, which would have a periphery in Europe, South America, and CANADA.

With the collapse of communism and the weakening of Russian dominance over Eastern Europe, Mackinder's theory could be considered a little out of date. Although Russia still maintains considerable influence and indeed some power over countries that were formerly members of the Soviet Union, that influence has waned measurably in Eastern Europe. If the heartland still exists, it no longer dominates a protective circle of support. The battle between Western capitalism and Eastern communism is now progressing toward a combining together, possibly through the EUROPEAN UNION, keeping distinct nationalities but becoming one Europe instead of two.

It could be argued that global mentalities and attitudes are changing. World dominance, imperialism and expansion may no longer be the driving forces behind national and international development, as much as the growing importance of economic integration, global trade, and financial stability. This does not necessarily mean that Mackinder's theory is no longer applicable. It could be that the pivotal heartland has just shifted from one means of control to another, where the new region of focus in the 21st century seems to be "he who controls China's markets, controls the world."

It remains to be seen just how necessary geography and topography really are to sound explanation and analysis of our political world. A general case can be made that such considerations are increasingly less important: that technological innovations in communications and transportation are making geographical constraints less constraining, at least for the industrialized world.

Goods and services are increasingly global in character, and national borders are increasingly porous, giving enormous advantage to administratively flexible market-states but harming and undermining those states that cannot or will not adapt to globalizing dynamics. Military technology for countries at the highest level is also less constrained than ever by geography, topography, and climate. The next generation of scientific-technical advances will accelerate such processes, making the old constraints imposed by geography and topography completely obsolete.

However, while geography may not seriously constrain the United States and a few other advanced societies, it will continue to constrain most of the states of the world most of the time.

## Georgia

**Map Page** 1121 **Area** 43,310 square mi (69,700 square km) **Population** 4,934,413 **Capital** T'bilisi **Highest Point** 17,064 ft (5,201 m) **Lowest Point** 0 m **GDP per capita** \$2,500 **Primary Natural Resources** forests, hydropower, manganese, iron ore, copper.

LOCATED IN THE REGION known as the Caucasus or Caucasia, Georgia is a small country, about the size of WEST VIRGINIA. To the north and northeast, Georgia borders the Russian republics of CHECHNYA, Ingushetia, and North Ossetia. Neighbors to the south are ARMENIA, AZERBAIJAN, and TURKEY. The shoreline of the BLACK SEA constitutes Georgia's entire western border. Georgia was absorbed into the Russian empire in the 19th century. Independent for three years (1918 to 1921) following the Russian Revolution, it was incorporated into the Soviet Union and became independent again in 1991.

The Georgian nation represents a fusion of local inhabitants with tribes infiltrating from Asia Minor in remote antiquity. There has also been an admixture of Greek, Scythian, Iranian, and Armenian elements. Ethnic groups in Georgia include Georgian (70.1 percent), Armenian (8.1 percent), Russian (6.3 percent), Azeri (5.7 percent), Ossetian (3 percent), Abkhaz (1.8 percent), and others (5 percent).

### THREE REGIONS

Georgia falls into three main structural regions, which originated in the vast earth movements of the Alpine folding period. In the north is the Greater Caucasus range, in the center a tectonic depression or trough, and in the south the mountains of Transcaucasia. All the southern flank of the Greater Caucasus range, usually regarded as the boundary of Europe and Asia, lies in Georgia, as far east as Mount Diklos-Mta. Although

the highest peak, ELBRUS, lies just over the boundary of the republic, many high peaks are on the crest line: Shkhara, 17,063 ft (5,201 m); Dzhangitau, 16,565 ft (5,049 m); Kazbek, 16,558 ft (5,047 m); and Ushba, 15,453 ft (4,710 m). Many of these peaks have extensive glaciers. Toward the west, approaching the narrow coastal strip along the Black Sea, the range becomes lower. South of the main range is a series of lower ranges, usually roughly parallel to it and separated from it and from each other by deep valleys and gorges. From west to east the chief of these ranges are Gagrinski, Bzybiski, Abkhaz, Kodorski, Svanetski, Metrelski, Lechkhumski, and Rachinski. Farther east, the Suramski Kartalinski and Nakhetinski ranges are perpendicular to the greater Caucasus.

The rivers, which mostly rise in the ice field, are many and fast-flowing, the largest being the Bzyb, Kodori, Inguri, Tskhenis-Tskali, and Rioni, which flow to the Black Sea and the Kura tributaries—Aragvi, Iori and Alazani—flowing to the Caspian. In the extreme northwest is the picturesque Lake Ritsa.

The tectonic trough is divided in two by a saddle formed by the Suramski range. To the west is the wedge-shaped lowland of Kolkhinda, the legendary land of the Golden Fleece. Rioni and other mountain rivers bring an enormous volume of water and silt, which have formed a widespread swamp. East of the Suramski saddle, the trough continues as a series of high, level plains, notably those of Gori and Rustavi, drained to the east by the Kura and its tributaries. The third region, in the south, consists of ranges and plateaus, often called the Lesser Caucasus.

Georgia's climate is affected by subtropical influences from the west and Mediterranean influences from the east. The Greater Caucasus range moderates local climate by serving as a barrier against cold air from the north. Warm, moist air from the Black Sea moves easily into the coastal lowlands from the west. Climatic zones are determined by distance from the Black Sea and by altitude.

Georgia's history is in some respects similar to Armenia's: In both cases small nations have successfully maintained their ancient cultures against successive invaders and regional overlords. Georgia's own Orthodox Christian Church played an important role in preserving the nation's identity, culture, and traditions. The Georgian group of languages is unique and does not belong to any of the major language families. From the 18th century to the present day, Georgia has from time to time turned to RUSSIA for protection and help: Russia's response over the years has varied according

to its interests. Since independence, the people of Georgia have endured periods of civil war related to the independence aspirations of the breakaway regions of Abkhazia and South Ossetia. Although diplomatic efforts have brought relative stability in recent years, tensions over both regions persist.

Georgia's main economic activities include the cultivation of agricultural products such as citrus fruits, tea, hazelnuts, and grapes; mining of manganese and copper; and output of a small industrial sector producing alcoholic and nonalcoholic beverages, metals, machinery, and chemicals. The country imports the bulk of its energy needs, including natural gas and oil products. Its only sizable internal energy resource is hydropower.

## Georgia

ONE OF THE 13 original American colonies, the state of Georgia was founded by General James Oglethorpe under a charter signed by King George II of England in June 1732. Georgia is bounded on the east by the ATLANTIC OCEAN and SOUTH CAROLINA, on the west by ALABAMA, on the south by FLORIDA, and on the north by NORTH CAROLINA and TENNESSEE. The state is 300 mi (482 km) north to south and 230 mi (370 km) east to west.

Known as the "Empire State of the South," Georgia's 57,906-square-mi (149,975-square-km) area makes it the largest state east of the MISSISSIPPI RIVER. It ranks tenth in population in the country. Atlanta (the capital), Augusta, Columbus, Savannah, Athens, Macon, and Albany are the largest cities in the state.

Georgia's climate is humid subtropical, with long, hot summers and short, mild winters. The state experiences rainfall throughout the year and snow falls occasionally in the northern section of the state, resulting in an annual average precipitation of 50 in (127 cm). During Georgia's hot summers, low levels of precipitation may lead to drought. The mean elevation of the state is 600 ft (182 m) above sea level. Georgia has an annual growing season that ranges from 185 days in the mountains to 250 days in the south.

Six physiographic areas make up the geography of Georgia: the Cumberland Plateau, also known as the Lookout Plateau, which is located in the northwestern section of the state; the Southern Valley and Ridge Region, which is an irregular section located between the Cumberland Plateau and the Georgia mountains; the Southern Blue Ridge Region, which includes sections of both the APPALACHIAN and Blue Ridge mountains; the Southern Piedmont Belt, which is located at the foot of the Georgia mountains, covering most of the northern part of the state; and the Atlantic Coastal Plain, also known as the Sea Island Region, and the East Gulf Coastal Plain, which together cover most of the southern half of the state. The section that divides the Atlantic Coastal Plain from the Piedmont is known as the Fall Line. In this area, the land abruptly drops to sea level, creating rapids and waterfalls that boats are unable to navigate. Georgia has four major soil areas: the Limestone Valleys and Uplands, the Piedmont Plateau, the Fall Line Hills, and the Coastal Plains. Overall, Georgia's soils tend to be sandy and clay loams, ranging from gray to dark red, covering gently rolling hills.

Georgia's major rivers are the Savannah, the Ogeechee, the Altamaha, the Suwannee, and the Chattahoochee. The state has no large natural lakes, but a number of man-made lakes have been created by damming river waters. The largest of Georgia's lakes are Lake Seminole; Walter F. George Reservoir; Lake Sidney Lanier; Lake Sinclair; Hartwell/Thurmond Lake, which is known as Hartwell in Georgia and as Thurmond in South Carolina; and West Point Lake, which Georgia shares with Alabama. Callaway Gardens, one of the state's major tourist attractions, is located near the Little White House in Warm Springs, where President Franklin Roosevelt died on April 12, 1945. Callaway Gardens is located in Pine Mountain, the southernmost foothills of the Appalachians.

Along with Florida, Georgia is home to the Okefenokee Swamp, also known as the Everglades, a 700-square-mi (1,812-square-km) area located in the south-

eastern corner of the state. The swamp was named by the Seminole natives who described it as Land of Trembling Earth. The eastern part of this swamp, which is called the Grand Prairie, is covered with various grasses and water lilies.

This former Confederate state was once known for its cotton output. By the beginning of the 21st century, Georgia's economy centered around the manufacturing and service industries. Atlanta, the largest city, is the major economic, communication, and transportation center of the American South. Also known as the Peach State, Georgia's farm products also include cotton, peanuts, tobacco, pecans, onions, corn, eggs, and soybeans. The state leads the nation in the production of paper and board, tufted textile products, and processed chicken and provides more than half of the resin and turpentine products for the entire world.

Approximately 67 percent of Georgia is forested with trees ranging from the southern pine forest that is home to slash and longleaf pines and live oaks to the cypress and tupelo found in the Georgia swamps, to the hardwoods found in the northern section of the state. Georgia's flowering trees include the redbud, the dogwood, and the azalea.

Wild animals found throughout the state of Georgia include deer, raccoon, opossum, fox and squirrel; black bears reside in the mountains and the southeastern section of the state. Game birds include ducks, geese, and quail, while the mockingbird and the wood thrush are the state's most common songbirds. Minerals found in the state include kaolin, granite, coal, sand, gravel, talc, soapstone, barite, bauxite, manganese, and clay.

## geostrophic winds

GHOSTROPHIC WINDS blow above the friction layer of the Earth, balanced between pressure gradient forces and the Coriolis force. *Geo*, meaning "Earth," and

*strophic*, or “turning,” refer to the Coriolis force of the Earth’s rotation. The Coriolis force causes wind to bend, eventually equalizing with the pressure gradient force. Geostrophic winds blow aloft and parallel to contour lines, or isobars. Isobars indicate varying gradients of pressure on weather maps, with different areas of pressure identified by isolines. Geostrophic winds occur aloft because land and water affect wind patterns in the friction layer of the atmosphere; they are more likely to occur when winds flow uninterrupted by frictional forces.

Wind is the movement of air molecules from one area of pressure to another. Air pressure is the mass of the air particles in an air parcel. Different pressure areas occur from the heating and cooling of the Earth’s surface, resulting in air parcels rising or sinking. In warm air, pressure increases, and in cold air, pressure declines. Land features and water can also cause pressure changes. The relationship between these differing pressure areas is called the pressure gradient.

Pressure gradient force causes air particles to flow from areas of high pressure to low pressure and seeks to reestablish equilibrium with the constant ideal pressure. The greater the difference in pressure, the faster the particles will move, thus the faster the wind speed.

The Coriolis force, named for French scientist Gaspard Coriolis, results from the Earth’s rotating on its axis. As the Earth rotates, the Coriolis force pulls wind from its intended path, causing it to deflect. This force grows stronger closer to the poles and has no effect at the equator. The Coriolis force affects any free object, such as an airplane or ocean current. In the Northern Hemisphere, the Coriolis force pulls winds to the right, in the Southern Hemisphere to the left. An object’s speed and latitude affect the degree of the Coriolis force, and as an object’s velocity increases, so does the Coriolis force. The Coriolis force affects only wind direction, not speed, and is more substantial over longer distances and larger regions.

Geostrophic winds result from the interaction of the pressure gradient force and the Coriolis force. Above the friction layer, winds are free from interfering obstacles that slow wind speeds and reduce the Coriolis force. Pressure gradient forces increase wind acceleration. As wind speeds increase, the effect of the Coriolis force increases, pulling winds farther and farther from intended paths.

The Coriolis force occurs only when pressure gradient forces set air into motion. Ultimately, the increasing forces of acceleration and direction counteract one another. In the Northern Hemisphere, the Coriolis

force pulls farther and farther to the right until it completely opposes the pressure gradient force, and the net force becomes zero. At that equilibrium, winds blow at a continuous speed, parallel to isobars.

Because geostrophic winds reflect isobaric delineations, wind speed measurements can help determine isobaric contours. Also, by using Buys-Ballot’s Law, an observer can determine the location of high and low pressure areas.

Dutch meteorologist Christoph Buys-Ballot determined the directional relationship between wind and different pressure areas. An observer standing with his or her back to the wind turns approximately 30 degrees to the left. To the observer’s left will be an area of low pressure, and an area of high pressure to the right. Normally observed winds are not often geostrophic, as friction and other forces affect these winds. But by studying geostrophic wind approximations above the friction layer of the atmosphere, meteorologists can learn more about different factors influencing real wind.

## Germany

**Map Page** 1131 **Area** 137,845 square mi (357,021 square km) **Population** 82,398,326 **Capital** Berlin **Highest Point** 9,721 ft (2,963 m) **Lowest Point** -11 ft (-3.54 m) **GDP per capita** \$26,000 **Primary Natural Resources** iron ore, coal, potash, timber, lignite.

THE FEDERAL REPUBLIC of Germany is one of the largest countries and has the largest population in Eu-

rope after RUSSIA. Germany borders the NETHERLANDS, BELGIUM, and LUXEMBOURG to the west; FRANCE to the southwest, SWITZERLAND and AUSTRIA to the south; the CZECH REPUBLIC to the southeast; POLAND to the east; and the Baltic Sea, DENMARK, and the North Sea to the north. Germany is a federal republic that reunited with the former German Democratic Republic in 1990. The legislature is a bicameral parliament consisting of the Bundestag, based on popular representation, and the Bundesrat, which represents Germany's 16 states, or Lander. The president serves as head of state, while the chancellor serves as the head of government. The major cities of Germany are Berlin, Bonn, Frankfurt am Main, Hamburg, Dusseldorf, Cologne, Munich, and Dresden.

Germany is divided into three regions: the northern lowlands, the central highlands, and the southern alpine region. The northern lowlands extend from east to west from the Baltic to the North Sea and southward to Wittenberg. The northern lowlands are mostly flat plains with marshes and lakes. The land is fertile and has been used for grazing and agriculture. The central highlands are mountainous and forested. The Harz Mountains straddle the center of Germany and once formed the border between East and West Germany, while the Erzgebirge Mountains form the boundary with the Czech Republic. To the west is the RUHR VALLEY, which contains Germany's mineral wealth and is the center of its coal and steel industries. In the center of Germany lies the Thuringian Forest. To the south are the Bavarian Alps, which form the border with Austria. The Black Forest lies in southwestern Germany in Bavaria.

Rivers play a significant role in the economic life of Germany. The RHINE, which carries more traffic than any other European river, flows northward from Switzerland, straddles between France and Germany, and empties to the North Sea. The Elbe River begins in the Czech Republic, flows through Hamburg, and empties in the North Sea. The Weser River begins in central Germany, flows through Bremen and Bremerhaven before emptying into the North Sea. The Oder and Neisse rivers form the boundary with Poland before emptying into the Baltic Sea. A network of canals called the Mittelland Canal connects the Elbe, Weser, and the Ems.

The climate in Germany is generally temperate, averaging 48 degrees F (9 degrees C). In January the average temperature ranges from 21 to 34 degrees F (-6 to 1 degree C), and in July the average temperature ranges from 61 to 68 degrees F (16 to 20 degrees C).

Winters and summers are wet, cool, and cloudy. The south receives the most precipitation with a yearly average of about 78 in (198 cm), mostly in the form of snow. The central uplands receive an average annual rainfall of 59 in (150 cm), while the northern lowlands receive 28 in (71 cm).

Humans have inhabited what is now Germany for at least 400,000 years, evidenced by the discovery of the *Homo Erectus* species known as the "Heidelberg Man." *Homo sapiens* remains have been traced to about 300,000 years. Between 1800 and 400 B.C.E., the Germanic tribes arose and established their dominance in the region.

The Roman historian Tacitus identified over 60 German tribes. Over the centuries, the Roman Empire kept watch over the Germanic tribes along its borders along the Rhine and the Danube. In 9 B.C.E., the Roman Empire met its worst military defeat at the Battle of Teutoburg Forest when three legions under Publius Varus were annihilated by an alliance of tribes under their leader Hermann. The disaster at Teutoburg Forest cost Rome its provinces east of the Rhine and ended its expansion. The weakness of Rome in the third and fourth centuries allowed the Germanic tribes to encroach into Roman territory in the west. In 476, Romulus Augustulus, the last emperor of the Western Roman Empire, was deposed by the German chieftain Odoacer. By the early Middle Ages, Italy and Western Europe were divided into Germanic kingdoms. The Roman Catholic Church, however became a civilizing influence upon the Germanic conquerors.

The history of medieval Germany is one of failed attempts to create a unified state. The Franks were the first German power that sought to dominate Central Europe. In 768, Charlemagne assumed leadership of the Franks and expanded his domains from the Danish peninsula to the north to the ADRIATIC SEA in the south and from Brittany in the west to the Elbe in the east. On Christmas Day in 800, Pope Leo III crowned Charlemagne Emperor of the Romans. Under Charlemagne, this new empire had the beginnings of a central government but fell under the dissension of his heirs. In 843 under the Treaty of Verdun, Charlemagne's empire was divided among his three grandsons. Charles the Bald inherited the Kingdom of the Franks, which became France. Lothair inherited the imperial title and received a region from the North Sea, which ran through the Rhine River and into Rome. Louis received Francia orientalis, which became Germany.

After centuries of conflict between competing dynasties, the imperial crown passed to the Habsburg

family in 1438, where it remained for the rest of the Holy Roman Empire's existence. The Habsburg rulers of Germany used the Holy Roman Empire, as purely a means to strengthen their family's domains in Austria, rather than to create a unified German state. The Habsburgs reached the apex of their power and prestige when Charles V inherited both the imperial crown, and the crown of Spain, which included its holdings in the Netherlands, Naples, and the Americas. At the same time, Charles V reaped the whirlwind of the Protestant Reformation, as Martin Luther defied the authority of the Roman Catholic Church in 1517. Germany's hopes of unification were dashed in 1555 through the Peace of Augsburg, which left each German ruler to decide the religion of his particular state. Germany and all of Europe became embroiled in religious warfare, culminating in the Thirty Years' War. The war ended with the Treaty of Westphalia, which confirmed the Peace of Augsburg, ensuring the sovereignty of the 300 states of the Holy Roman Empire.

Out of the numerous German principalities arose Prussia, which rivaled with Austria for supremacy. Prussia grew from the traditional electorate of Brandenburg in northeastern Germany with holdings along the Baltic coast. Since the 17th century, the electors of Brandenburg-Prussia strengthened their armies into a well-trained fighting force led by its aristocratic class, known as the Junkers. The Prussian army distinguished itself in wars against Poland and SWEDEN. In 1701, Frederick, the elector of Brandenburg, as proof of his state's rise in fortunes, declared himself the King of Prussia.

In 1740, Frederick II (later, the Great) took advantage of the death of Charles VI and the succession of his daughter, Maria Theresa, by invading the Austrian province of Silesia, inaugurating the War of the Austrian Succession. By the Treaty of Aachen in 1748, Frederick retained Silesia. Maria Theresa launched another war, the Seven Years', to regain Silesia, only to end in defeat. Victory in these two wars assured Prussia of a place among the great powers of Europe. Prussia enhanced its prestige further by taking part in the Polish Partitions between 1772 and 1795.

The French Revolution and the resulting Napoleonic Wars were a turning point in the history of Germany. Prussia and Austria joined Britain and Russia in fighting Napoleon's forces from mastering all Europe and the revolutionary ideas he took with him. The rise of Napoleon fundamentally altered the arrangement of the German states. Accepting political reality, Francis II put an end to the Holy Roman Empire and declared

*Neuschwanstein Castle in Germany reflects the country's merging of old and new into a unified and powerful state.*

himself emperor of Austria. Prussia suffered major defeats at the Battle of Jena in 1807 and lost significant territories in the west and its Polish holdings in the east. In 1813, the German states united against Napoleon and defeated him at the Battle of the Nations, paving the way for his downfall.

The Congress of Vienna in 1815 attempted to restore some of the balance of power that was disrupted by the French Revolution and Napoleon. Even though the Holy Roman Empire was never restored, the German states were reorganized into the German Confederation under Austrian leadership as a result of the diplomacy of Klaus von Metternich. Prussia regained some of its eastern territories and acquired the Rhineland. Prussia again asserted its claim leadership through the creation of the Zollverein, or customs union, which eliminated trade barriers among the German states. Conservative reaction was evident in the Carlsbad Decrees passed in 1819, which forbade student associations and dissent. Legitimacy was the order of the day.

The influence of the French Revolution continued to persist, however. Nationalist movements arose among intellectuals who wished to unite Germany based on language and culture. Liberals wanted a government based on limited government, popular sovereignty, political rights, and freedom and equality for all individuals. In 1848, revolution once more spread throughout Europe. In Frankfurt, a group of intellectuals formed an assembly to envision a unified state that

The Brandenburg Gate in Berlin, Germany, has become a symbol of the 1990 reunification of East and West Germany.

carried those ideals and, with the failure of the Frankfurt Assembly, was Germany's last chance to create a unified democratic state.

What the Frankfurt Assembly could not accomplish through resolutions (the unification of Germany) was made possible through political maneuvering and skillful diplomacy. In 1858, Otto von Bismarck rose as chancellor of Prussia. Between 1864 and 1871, his sole purpose was the strengthening of securing Prussian supremacy within the Confederation. At the conclusion of the Seven Years' War, Bismarck declared an end to the German Confederation and expelled Austria from leadership among the German states. Bismarck consolidated Prussian influence by creating the North German Confederation in 1867, which was a federal entity of northern German states under the leadership of the king of Prussia. The Franco-Prussian War in 1870 resulted from Bismarck's machinations to incite France into declaring war against Prussia, bringing the southern German states into his fold. By 1871, Prussia had defeated France, and King William I of Prussia was declared Emperor of Germany, with Bismarck as his chancellor.

The new German Empire was a federal structure that was created by the consent of the princes, rather than the German people. Voting and representation were based on a formula that favored the upper classes. The federal structure overwhelmingly represented Prussia, the largest state in the empire. Between 1871 and 1878 Bismarck launched an unsuccessful campaign against the Catholic Church in Germany, called the *Kulturkampf*, by expelling Catholic religious

orders and imposing a secular educational system. Keeping an eye against revolutionary movements, Bismarck established the beginnings of a welfare state by creating workers' compensation laws and a pension system for retired workers. After unification, German economic productivity rose, outstripping that of its neighbors. In foreign policy, Bismarck sought to assure other European powers that Germany had no territorial or colonial ambitions and sought to live peacefully.

When Emperor William II ascended to the throne, he sought to take Germany on a different course. After dismissing Bismarck, ending his decades of service as chancellor, Germany embarked upon an aggressive foreign policy. Through *Weltpolitik*, or geopolitics, Germany began acquiring colonies and enlarging its navy, which caused great concern for Britain. Bismarck's successors caused Germany to become diplomatically isolated in Europe. By unwisely giving full support to Austria in its dispute with Serbia in 1914, World War I erupted, whose devastating results were unforeseen. After four years of trench warfare and the deprivations imposed by the British blockade, Germany erupted into revolution. William II abdicated and fled to Holland in 1918.

The Weimar Republic replaced the monarchy in 1918 and sued for an armistice. The Treaty of Versailles, which ended World War I, imposed harsh penalties for Germany. The treaty stripped Germany of territory as well as its colonies, imposed occupation in the Rhineland, abolished its navy, imposed restrictions on its army, and imposed enormous reparations, which severely devalued its currency. The German people viewed the Weimar Republic as complicit in Germany's degradation. In the early 1920s, Germany was caught in the struggles between the communists and radical right-wing forces in their battles for control. Economic stability returned in 1925 but was shattered in 1929 with the coming of the Great Depression, bring Germany to a dark chapter in its history.

In 1933, after unsuccessful attempts by succeeding governments to solve Germany's economic woes, 37 percent of the voters elected the National Socialist Party into the Reichstag. Adolf Hitler, a former German corporal and rising star of the Nazis, was invited to become chancellor of Germany by conservatives who sought to take advantage of his growing popularity. Hitler began consolidating his grip on the German government through taking on emergency powers after the Reichstag fire, which was blamed on the Communists. The Enabling Act gave the Nazis full power and eliminated all political opposition. Hitler then turned

on the Jews, whom he blamed for Germany's ills, by eliminating them from government positions. The Nuremberg Laws passed in 1934 removed Jews from German economic and social spheres.

In 1936, Hitler began the territorial aggrandizement of Germany by reoccupying the Rhineland. In 1938, the Anschluss of Austria was achieved, uniting the two German-speaking countries. Hitler succeeded in the dismemberment of Czechoslovakia without Allied opposition. In 1939, Germany invaded Poland, setting off World War II. In less than two years, Germany conquered most of Europe. While simultaneously prosecuting a war against the Allies, Hitler and the Nazis carried forward the Final Solution and attempted to eradicate all European Jews by constructing concentration camps throughout Europe. By the end of the war, the Nazis had murdered 6 million Jews, including Poles, Gypsies, and other minorities. World War II ended with Germany's defeat and occupation by the United States, Britain, France, and the Soviet Union.

In 1949, two German states arose. The Federal Republic of Germany was composed of American, British, and French sectors in the west, and the German Democratic Republic consisted of the Soviet sector in the east. The city of Berlin remained occupied by the four Allied countries until 1994. West Germany was a capitalist democratic state whose economy recovered in the immediate postwar years. Bonn served as the capital of West Germany until a decision could be reached regarding reunification.

East Germany, with its capital in East Berlin, was a bulwark of communism that had shut its borders with the West by the 1960s. Berlin remained the source of Cold War tensions between the Soviet Union and the West. By the 1970s, West Germany began the policy of *Ostpolitik*, which opened relations with East Germany and Eastern Europe. In 1989, with reforms in the Soviet Union and growing popular discontent, the Iron Curtain came down with the dismantling of the Berlin Wall and the opening of borders. By 1990, east and west were reunified within the Federal Republic of Germany. Since then, the costs of reunification have been enormous in bringing eastern Germany to Western standards, engendering discontent. In 1999, Germany moved its capital from Bonn to Berlin and joined eleven other countries in the EUROPEAN UNION in adopting the euro as the unified currency.

Though initially joining with the United States in solidarity after the attacks in New York and near Washington, D.C., on September 11, 2001, Germany

opposed the American and British invasion of Iraq in 2003.

Germany has the third largest economy in the world after the United States and Japan. Throughout the postwar period West Germany has instituted a generous welfare state that shares its wealth with its citizens. However, the costs of reunification and the rise of its aging population have put pressure on the German government to cut back on its benefits.

## Ghana

**Map Page** 1113 **Area** 92,090 square mi (238,500 square km) **Population** 20,467,747 **Capital** Accra **Highest Point** 2,904 ft (885 m) **Lowest Point** 0 m **GDP per capita** \$280 **Primary Natural Resources** gold, bauxite, diamonds, hydropower.

GHANA IS LOCATED in west-central Africa and is bordered by CÔTE D'IVOIRE to the west, TOGO to the east, and BURKINA FASO to the north. The Gulf of Guinea of the ATLANTIC OCEAN washes Ghana's southern shore. Ghana, formerly called the Gold Coast, was a British colony until March 6, 1957, when it gained independence. A country slightly smaller than the state of OREGON, it became the first nation in sub-Saharan Africa to gain political independence from a European colonial power. A densely populated and lowland country, its main export was the production of cocoa, with a little mining, at independence. It supplied the

chocolate industries in Europe with their important raw material, cocoa. It assumed the name Ghana at independence and began to play an important role in African struggle for independence and national liberation.

Flat plains and gently rolling hills characterize Ghana. Its forests cover 28 percent of the country's area, while 26 percent is farmed. The country is divided into five distinct geographical regions. Coastal plains stretch across the southern portion of the country, featuring low sandy beaches interspersed with salt-water lagoons. A forested plateau region consisting of the Ashanti uplands and the Kwahu Plateau is located inland, in southwest and south central Ghana. The hilly Akwapim-Togo Ranges run north to south along the country's eastern border. While the Volta Basin takes up most of central Ghana, high plains characterize the northern third of the country. Its main river is the Volta, which is formed in the center of the country by the confluence of the Black Volta and the White Volta.

The Volta enters the Gulf of Guinea at Ada in southeastern Ghana. The construction of the Akosombo dam in 1961 on the Volta formed Lake Volta. The lake covers an area of 3,275 sq mi (8,482 sq km), making it one of the world's largest artificial lakes. The two major tributaries of the Volta are the Oti and Afram rivers. Together, the rivers drain the Volta Basin. Ghana's other significant river systems are the Densu, Birim, Pra, and Ankobra. All empty into the Gulf of Guinea. Ghana's rivers are navigable only by small crafts, with the exception of the Volta.

Southern Ghana contains evergreen and semi-deciduous forests, consisting of tall silk cottons, kolas, and valuable West African hardwoods such as mahogany, odum, and ebony. About two-thirds of the country is covered by savanna characterized by shea trees, acacias, and baobabs. Oil palm is found throughout the south and the Ashanti uplands, and the lagoons of the coast contain mangroves. Once plentiful throughout the savanna, large mammals such as elephants and lions are now rare and largely confined to nature reserves. The forest regions are habitats for monkeys, snakes, and antelopes. Some of its major rivers contain crocodiles. There are more than 725 bird species in Ghana.

Ghana is a tropical country with distinctive wet and dry climate seasons (with regional variations). The north experiences one long rainy season from March until November, when a hot, Saharan wind known as the harmattan blows from the north and brings the dry

season. The south experiences two rainy seasons: one from April to July, and then—after intermittent rains in August—another from September to November. The northern part, like in Nigeria, is drier than the south, with the exception of the coastal area around Accra.

Despite continuous migration into urban areas, 64 percent of the population still resides in rural communities. The main occupations in the rural areas are farming, herding, and fishing. In the cities, most people work in the service sector or in manufacturing. The country's major cities are Accra, the national capital; Kumasi, the principal city of the Ashanti region; Tema, an industrial city and Ghana's major port; Sekondi and Takoradi, the coastal twin cities; Tamale, a northern trade center; and the college town of Cape Coast.

Upon independence in 1957, Kwame Nkrumah tried a socialist economic reform without success. Ghana, like most developing countries, has witnessed many military interventions, which invariably hampered development. As such, it experienced severe economic decline as a result of political instability. By the mid-1980s, however, economic recovery programs were put in place to encourage and expand private sector investments and more important, to satisfy both the International Monetary Fund and the World Bank reform programs. Since the mid-1980s the government has promoted industries using local raw materials and private investment in food production. Since 1990, Ghana's economy has grown at an average of 4.2 percent each year.

## Gibraltar

GIBRALTAR IS AN overseas territory of the UNITED KINGDOM. Historically known as one of the Pillars of Hercules, the Rock of Gibraltar has guarded the entrance to the Mediterranean world since the beginning of Western civilization. Held by Great Britain since 1704 (formally since 1713), the peninsula remains one

of Britain's last overseas territories, with little indication of change in the near future, despite intense pressure by the Spanish government.

The Rock is situated at the end of a peninsula, 2.8 mi (4.4 km) in length, that juts out into the Alborán Sea (the westernmost extension of the MEDITERRANEAN SEA), terminating in Europa Point. The other "pillar," Cape Ceuta (or Punta Almina), lies 9 mi (14.5 km) across the Strait of Gibraltar, on the north coast of Africa. To the west are the more protected waters of the Bay of Algeciras, and the man-made Gibraltar Harbor, around which rises the military and administrative community of the colony. The eastern face of the rock is much more perpendicular, as are the northern and southern approaches, underlining the defensive importance of the rock, which itself is composed of dense limestone arranged in thick rock beds. Gibraltar is connected to the mainland of Spain by a narrow isthmus, low and sandy, across which daily migrants travel from the nearby Spanish town of La Línea.

The Rock has been extensively fortified and modified over the centuries, with about 10 mi (16 km) of tunnels, casements for heavy artillery (especially during World War II), a canal cut across the isthmus, and even a narrow landing strip jutting into the Bay of Algeciras on the western side of the peninsula. The naval harbor and dockyard has recently been expanded with a land reclamation project called the Europort, increasing Gibraltar's total land area by 10 percent.

Having no flat land of any consequence, Gibraltar must import all of its food needs. The colony's economy depends instead on tourism, offshore banking and finance, and industries related to shipping.

## HISTORY OF THE ROCK

The Rock received its present name from Arab conquerors in the 8th century, who named it the Rock of Tariq (gebel al Tariq), after one of their generals, Tariq ibn-Ziyad. It was taken by Spanish forces of the Reconquista in 1462 and fortified by Carlos I (Emperor Charles V) using the most advanced German engineers. Occupied by a combined Anglo-Dutch naval force in 1704, during the War of Spanish Succession, Gibraltar was formally ceded to Britain in 1713. Britain maintained its garrison throughout the 18th century, despite repeated Spanish attacks, notably the famous four-year siege during the American Revolutionary War, and Gibraltar was formally declared a crown colony in 1830. Despite attacks from the air by both German and Italian airplanes in World War II, General Dwight Eisenhower kept his headquarters there during the Al-

lied invasion of North Africa. A referendum in 1967 left no doubt that the colony's residents wished to remain British subjects, as a fully self-governing dependent territory. A scheme for "total shared sovereignty" proposed by the Spanish government received a similar overwhelming "no" in a vote held in 2002.

## glaciation

THE ACTION OF GLACIERS has made a huge difference in the appearance of the Earth's surface. Changes in the land from the action of glaciers is called glaciation. A glacier is a moving mass of ice, air, water, rock and sediment. Glaciers flow very slowly with gravity created by their own mass. During the last Ice Age, more than 19 million sq mi (50 million sq km) of the Earth's surface was influenced by glaciers. Glaciers form when snow builds up over a period of many years. If there is more accumulation than melting, a glacier will form. The weight of the snow compresses the lowest layers, changing the snow to ice. The ice eventually becomes thick enough to begin moving under the pressure of its own weight.

A glacier always moves in the same direction. The leading edge of the glacier is known as the terminus, the nose, or the snout. When a glacier retreats, it does not move backward. The terminus retreats because the glacier is melting at a faster rate than it is moving.

There are several types of glaciers. Ice sheets are enormous masses of ice that cover all land features except the tops of the highest mountains. They are found only in ANTARCTICA and GREENLAND. Ice shelves extend over the sea and surround the entire continent of ANTARCTICA. Ice caps are miniature ice sheets in polar and subpolar regions. Mountain glaciers develop in high mountains and flow down. They are found in CANADA, ALASKA, in the ANDES of South America, the HIMALAYAS of Asia, and in Antarctica. Valley glaciers originate from mountain glaciers. They fill the valley, often flowing to the sea. Piedmont glaciers happen when valley glaciers spill over onto flat plains and spread out. Cirque glaciers occupy bowl-like hollows

called cirques. They are usually found high on mountainsides. Hanging glaciers cling to the steep sides of mountains. They often cause avalanches in the ALPS. Tidewater glaciers are those valley glaciers that reach out into the sea. There calving occurs, which means pieces of ice break off and float in the water.

Glaciers can change the landscape in two ways. They can cause erosional landforms or depositional landforms. Erosional landforms can be created in two ways—by scouring or plucking. When rock and sediment frozen into the bottom surface of the glacier scrapes or scours the Earth's surface, it works like sandpaper. Striations, also known as glacial grooves, are deep scratches carved into the surface of the rock. Plucking removes material from the surface of the earth. It has more effect when there is loose material on the surface. The two processes sometimes overlap.

Glaciers can cause cirques, which are scoop-shaped bowls. Cirques sometimes fill with water, forming lakes known as tarns. U-shaped valleys form when glaciers widen already-existing valleys. Glacial basins are formed where thick, fast-moving warm ice excavates hollows in bedrock. A hanging valley forms when a small tributary glacier erodes a valley so the elevation of the valley floor is higher than that of the valley of the main river of ice. It often contains a waterfall. Aretes, or steep-sided ridges, are formed by two glaciers eroding opposite sides of a ridge.

Depositional landforms are formed when the glacier deposits rock, soil, and other materials. A moraine is an example of a depositional landform. It is an accumulation of materials deposited by glaciers. Moraines usually contain all sizes of particles, ranging from large boulders to fine silt.

There are different types of moraines. An end moraine is made up of material deposited at the snout of the glacier. End moraines are either terminal moraines or recessional moraines. A terminal moraine marks the furthest extent to which the glacier advanced and is found at the lowest elevation. A recessional moraine forms as a glacier pauses during a period of retreat. It is usually located at a higher elevation. A lateral moraine is built up along the sides of an alpine glacier. A medial moraine can form where two glaciers flow together. A till plain, a relatively large, flat plain, is formed when a sheet of ice separates from the main body of the glacier and melts in place.

Any sediment it contains is dropped, so till plains can contain large boulders. When a glacier retreats, hill-shaped deposits known as drumlins occur. A drumlin is shaped like the bowl of a spoon, with the narrow

end pointing to the general direction in which the glacier retreated.

Most glaciation has occurred during an Ice Age. There have been several Ice Ages throughout history, but the most recent began in the Northern Hemisphere about 2.5 million years ago. Climatic changes bring about an Ice Age, when temperatures become cooler. Other factors that can contribute to an Ice Age include tectonic activity, or changes within the Earth, including movement of land masses and volcanic eruptions. The angle at which the sun's rays strike the Earth also has to be taken into account.

Scientists believe we may be living in an interglacial interval within an Ice Age. Over 75 percent of the Earth's water is frozen. Areas with large glacial sheets include Antarctica and GREENLAND. Here huge ice sheets cover all land but the tips of the highest mountains. The Greenland Ice Sheet is growing smaller because of a gradual rise of temperature in that area in the past 100 years. Glaciers also exist in areas considered warm. In the mountainous areas of the northwestern UNITED STATES, NEW ZEALAND, and CHILE, there are large valley glacial systems. These glaciers will survive as long as the accumulation of snow exceeds the melting of the ice. Glaciers in temperate climates like this receive a large amount of snow in winter, which compensates for the fact that melting does occur in summer. If all the world's glaciers suddenly melted, there would be catastrophic results. Florida would consist of a few tiny islands. Many of the world's largest seaports would be underwater.

## global warming

GLOBAL WARMING IS an increase in the temperature of the Earth due to an increase in greenhouse gases that reduce natural cooling. Periodically, the natural changes in the Earth's climate have produced increases

and decreases in average temperature and the changes have altered the climate of the Earth. The current debate over global warming centers around the likelihood that industrial greenhouse gases are triggering global warming outside the Earth's natural cycle. The debate is both scientific and political, and the consequences are economic, social, and ecological. For example, during the presidential debates of 2000, candidate George W. Bush indicated that the scientific evidence for global warming was inconclusive at best, and that conclusions still needed to be established. As president in the summer of 2001, he withdrew the UNITED STATES from the Kyoto Protocol, an international agreement seeking national limits on greenhouses gases. Then he asked the National Academy of Sciences to examine the science of climate change. The academy reported in 2002 that industrial factors were, in fact, altering the climate.

### EVIDENCE FOR GLOBAL WARMING

Since around 1900, the Earth's temperature has risen about 1.1 degrees F (0.6 degrees C). The increase over the final 40 years of the 20th century was almost half of the total rise over a century. The rate of warming was greater than at any period in the preceding 400-600 years. The 1990s experienced 7 of the 10 warmest years of the century, including the hottest year—1998—since record keeping began over a century before. Mountain glaciers were receding, the Arctic ice pack decreased 40 percent in four decades, and sea levels rose during the previous century at a rate three times as fast as the rates of the preceding 3,000 years. Animals and plants were altering their ranges and behavior. Extreme weather (drought and storms and floods) became more prevalent and more extreme.

The Intergovernmental Panel on Climate Change reported in 2001 that regional climate changes, especially rising temperatures, had already begun to affect many parts of the world. Freezes came later in the year, permafrost was melting, and rivers and lakes were thawing earlier. Growing seasons increased in the mid-to high latitudes as plant and animal ranges shifted poleward and upward and animals and plants changed mating times. The panel's report rested on the examination of long-term studies, normally 20 years or more. The studies consistently confirmed the models. The study rejected chance as a cause in the direction of change, but it did not discount as a reason for magnitude.

The projected impacts, as warming continues, varies by REGION. Ocean and sea levels continue to rise,

heat waves and droughts become more common. as does conflict over water, weather such as floods is more severe, and heat-related illnesses and death and insect- and rodent-borne infectious diseases spread to areas previously without them. Greenhouse gases also damage the world's forests, increasing the amount of carbon dioxide as the forests cleanse less. Some of the measures to counter the emission of carbon dioxide, methane, and nitrous oxides include cleaner cars, alternative fuels, renewable energy sources, and an end to clear-cutting.

### SKEPTICISM AND DEBATE

Richard S. Lindzen, Alfred P. Sloan Professor of Meteorology at the Massachusetts Institute of Technology, says that there seems to be a consensus among the informed populace that global warming is real, as indicated by the upsurge in diplomatic activity. He acknowledges that greenhouse gases have increased, with carbon dioxide increasing 50 percent over the past century; he does challenge the implications and assumptions. He contends that there is little scientific evidence for the popular scenarios of catastrophe. In fact, the literature from hydrologists, economists, and agronomists indicates that adjustments would be fairly simple.

He grants that carbon dioxide levels have risen since 1800, based on evidence from ice cores and atmospheric sampling. The rate has slowed since the 1970s though. And the future depends on human choice—increased use of coal could cause a doubling by 2030. The solution is technology, and Lindzen advocates better nuclear reactors.

After all, the surface temperature has fluctuated within that one degree for billions of years. And the Earth has long had periods with higher carbon dioxide levels than the dire predictions forecast for the coming centuries. A skeptic's history of global warming acknowledges that 19th-century studies did note the possibility of industrial gases increasing warming. But the methodological problems were also noted. And climatologists discounted the theory. In fact, cooling in the 1950s and 1960s caused a concern in the 1970s that the world could be entering a period of cooling, not the warming of the 1980s and 1990s.

Mostly, the crisis of cooling passed with little political or scientific interest. Rising temperatures ended the hysteria. The Geophysical Fluid Dynamics Laboratory at Princeton and other institutions continued to model change and predict warming, but it remained an academic exercise until 1988. In the summer of 1988,

James Hansen of the Goddard Institute for Space Studies testified before the Senate Committee on Science, Technology and Space, saying that he was sure that temperatures had risen and greenhouse warming was occurring. It was a warm summer, and temperatures had risen in the 1970s faster than an even increase in carbon dioxide would warrant. Hansen cited no cause and effect relationship. Initially the climate-modeling experts criticized Hansen for trying to use shaky modeled data as the basis for public policy. Still, the community acknowledged that the warming model wasn't impossible.

Environmental groups seized on Hansen's testimony, making "global warming" a battle cry, a marketing tool. The Green lobby in the United States soon had a budget of several hundred million dollars and 50,000 employees. The media went along because the Green catchphrases were easier to understand and sold more papers than the abstruse technical debate. For the Greens, the burden of proof was absolute. They construed the scientific inability to disprove warming as validation of their nightmare scenarios. And scientists other than Hansen supported the model by acknowledging that increasing carbon dioxide probably would cause warming, but most remained skeptical about huge amounts and huge impacts. Politicians joined the effort, as did performers and other media personalities. The media in Europe and the United States by 1989 were declaring a scientific consensus.

As the movement grew, with politicians and others clamoring for saving Mother Earth, more skeptical scientists attempted to redress the balance. Reports in *Forbes* and *Reader's Digest* indicated that there really wasn't the scientific consensus the advocacy groups professed. The *Bulletin of the American Meteorological Society's* series supporting the environmentalists generated counterarguments from skeptics. A Gallup poll of climate scientists in the American Meteorological Society and in the American Geophysical Union indicated that 49 percent doubted man-made warming data, 18 percent accepted that some had occurred, and a third didn't know.

The warming advocates countered. A geologist at Greenpeace, Jeremy Legett, attacked the critics. Popular writings proliferated. George Mitchell, Senate majority leader and father of a prominent environmental activist, produced *World on Fire: Saving an Endangered Earth*; Senator Al Gore wrote *Earth in the Balance: Ecology and the Human Spirit*. The Union of Concerned Scientists, originally a nuclear disarmament group, then a nuclear power opponent, turned to the

global warming issue. Its petition citing global warming as the greatest risk to humanity got 700 signers, including members of the National Academy of Sciences and Nobel laureates. Most were not climatologists. And the petition called for renewed work on nuclear power.

Skepticism increased among the scientists even as consensus grew among the environmentalists and politicians kept the bandwagon rolling, reiterating the claims of scientific unanimity.

### SCIENTIFIC DOWNSIDE

The downside of making a political issue out of science is that it weakens the science in question. Funding for climate research actually decreased as the growth of researchers and programs was faster than the growth in funding. And one string attached was that the research must have the right result. Government money and government power were tied to one side of the debate. And industry got onto the bandwagon, especially industries that stood to profit by enhancing their image as environmentally responsible or industries such as waste management companies that had a direct economic benefit. Utilities could broaden the base on which they got profits. And environmental improvement was a \$1.7-trillion-a-decade enterprise.

As a final note, the whole question of modeling is confused by the tendency of many to believe that the great increases in computing power over the past decade or so have allowed the models to be accurate. The experts know that the complexity of the system is such that even this great computing capacity is insufficient to even approximate an accurate model. Without a good model, there is no solid basis for any conclusion. Just a vast waste of resources that could be better employed elsewhere.

### THE KYOTO PROTOCOL

In December 1997, more than 150 nations signed the first legally binding treaty aimed at cutting emissions of the main greenhouse gases believed to contribute to global warming. The meeting in Kyoto, JAPAN, though, left much of the detail about how it would be implemented to future talks. These dragged on, reaching a crisis in The Hague, NETHERLANDS, in November 2000 when the United States and the EUROPEAN UNION failed to agree and talks broke down. President Bush soon afterward announced that he was pulling the United States out of the deal altogether. Since America produced a quarter of greenhouse gases, that was a big blow, but the other nations decided to carry on, and

they finally reached agreement in Marrakech, MOROCCO, in November 2001.

Under the terms of the protocol, industrialized nations committed themselves to a range of targets to reduce emissions between 1990, the base year, and 2010. The world targets ranged from an average 8 percent cut for most of Europe up to a 10 percent increase for ICELAND and an 8 percent increase for AUSTRALIA. (The United States originally committed itself to a 7 percent cut.) The members of the European Union agreed to parcel out their entitlement so that countries such as IRELAND and GREECE could increase their emissions, while Britain, GERMANY, and others faced cutbacks.

Global warming is a highly charged political and economic issue. Third-world and developing nations contended that only the developed nations were in a position to afford reforms and technology; developing nations were not. Besides, the developed nations generated most of the gases and were the beneficiaries. Why should developing nations be penalized for following the industrialization path that brought wealth to the developed ones? Industrialized nations argued that the controls would be futile unless all nations cut back, even the developing ones. The United States contended that unequal standards would give developing nations a trade advantage. Domestic companies might desert the United States for countries without limits. Developing nations did win their demand for an exemption. The U.S. Senate voted 95–0 not to ratify any treaty that would not apply the same standards to all signatories.

### THE TIPPING POINT

In 2004, the U.S. Department of Defense jumped onto the global warming bandwagon. It reported evidence that the ocean-atmosphere system that determines the world climate, rather than shifting gradually over long periods of time, had historically moved quickly, within a decade or less, from one condition to another. The question for the department became how close the climate system might be to the threshold of another rapid shift. The explanation was that the current that brings tropical water and warm air to northern Europe and the eastern United States might be diluting because of increased cold water as glaciers melt and alter the ocean's salinity. Potentially, the current could collapse.

Earlier global warming, not caused by human impacts of course, replicated the human industrial centuries. As the Ice Age ended 13,000 years before, Greenland began warming, the current apparently shut down, and a mini Ice Age ensued, lasting 1,300 years. That was the Younger Dryas period.

Although the Younger Dryas ice age was natural, the climatologists in 2001 were more inclined to attribute similar conditions during the previous half century of global warming to human influence. They cited shrinking Arctic ice, melting glaciers in the ALPS, earlier springs in northern regions. They attributed these to the burning of fossil fuels (coal and petroleum), which releases heat-trapping carbon dioxide. When the climate experts met in 2001, they were worried about the consequences for future generations. Then came the tipping point theory. At some point in a process, the threshold is reached, and gradual change tips abruptly in the new direction.

### THE DAY AFTER TOMORROW

The National Academy of Sciences in 2002 reported that human activity could be the trigger of a new ice age from global warming. At the World Economic Forum at Davos, Switzerland, in 2003, Robert Gagosian of the Woods Hole Oceanographic Institution in Massachusetts strongly encouraged examination of the implications of a tipping point that could occur within two decades. Others alarmed at the possibility included billionaire Gary Comer of Land's End, who made climate change one of his philanthropies. In Hollywood, 20th Century Fox was preparing to release *The Day After Tomorrow*, a disaster movie set in the Ice Age caused by global warming. Not all scientists agreed, of course, but the momentum was shifting; even the cautious Department of Defense discerned a real threat from global warming.

While the scientists disputed with each other, the Pentagon defined climate change as a national security threat that could arrive as early as 2020. Megadroughts, nuclear war, mass starvation—these were some of the consequences of wars for river valleys and other sources of water and food. Once past the tipping point, change could occur within three to five years, bringing on another ice age. The Pentagon ceded that the probability of such consequences is unknown, probably quite small, but the risk is so severe that there is no option of assuming that it's a myth or bad science.

## globalization

**GLOBALIZATION** IS A term that is used quite frequently but whose meaning remains obscure. One definition of globalization is that is a process of complex interconnections between societies, cultures, institutions, and individuals that takes place worldwide. It also describes the increased mobility of goods, services, labor, technology, and capital. Although globalization is not a new development, it has rapidly increased with the introduction of new technologies. Globalization is often referred to as a contemporary or modern phenomenon, but it can also be studied from a historical perspective; the result of human innovation and technological progress (biotechnologies, miniaturization, digitalization, and photonics). These activities represent more than just the simple globalization of economic activity; they refer to the increasing integration of economies and societies across the world. Unfortunately, not everyone is represented equally in the globalization process as it is affected by wealth, access to global communication media, work, financial assets, and cultural norms.

Therefore, the processes of globalization have been reshaping the geography of the global economy. Globalization is a process in which geographic distances become less a factor in the sustaining of rigid land borders, long-distance economics, and political and socio-cultural relationships. Networks of relationships and cooperation cross land borders and oceans and occur worldwide. As globalization grows, geographic distance is less of a factor as the Earth does not really shrink, but "relative" distances do. Therefore, worldwide networks of agreements/cooperation can be established.

The transformative ability of the globalization process has commonly been associated with both material outcomes in such specific spatial units as locali-

ties, regions, and nation-states and peculiar discursive practices by societal partners. At the opposite, many researchers consider that globalization is associated with the declining influence of space in relationships among societies.

The debate on the ideology of globalization can be categorized into four different areas: 1) Free trade globalization is a way to enhance prosperity; 2) the adverse view: the potential dangers of globalization include increasing inequalities, marginalization of some regions or countries, social exclusion, crisis tendencies and simultaneous loss of political control; 3) globalization is thought of as a myth since the theory is not justified by the actual development; and 4) lastly, some economists view globalization as nothing new, as economic affiliation is as intense today as it was before World War I, 100 years ago.

Globalization can also be thought of as an ideology. The slogan of globalization is "Either globalize or perish." As an ideology, globalization implies both the inevitability and the desirability of the tendency toward integration, and not the adverse. On one hand, globalization has been accepted as the unavoidable pathway to economic prosperity and success. If a national country's economy is not performing well, it must be because the economy does not have "enough" economic globalization. On the other hand, anti-globalization views economic globalization as the cause of socioeconomic malaise.

### EMBEDDED AND DISEMBEDDED CAPITALISM

Finance and transnational corporations are the core subjects of economic geography. Any viable geography of finance must have something credible to say about market patterns and processes. The power exerted by finance is represented by the growing role of capital markets in the globalization processes (the rise and spread of institutional investors). The national specificity of capital markets explains why there is not a truly global capital market.

To some people, globalization means the ability of transnational corporations, through the use of free trade agreements and free trade zones, to transform space. Financial liberalization enhances capital mobility and shapes global values. In this view, transnational corporations attempt to dominate the world through the eradication of governmental controls and the homogenization of economies for their own profits, while marginalizing the rest.

The expansion of the role of transnational corporations through the mechanism of foreign direct invest-

ment in the world economy is the driving force behind globalization. Furthermore, globalization increases the access to global resources for a small corporate elite. Globalization means the concentration of power and wealth in the few hands of multinational corporations whose only mandate is profit (shareholder value creation). As a result, this leads to disempowerment of civil society and the homogenization of culture worldwide.

From a cultural perspective, there are two positions taken for and against the phenomenon of globalization. It is thought that globalization will lead to a homogenization of culture as people around the world will devalue their local culture and adopt American or Westernized ways. However, the goal of globalization is not that the entire world would become Westernized and capitalist, but that the Western culture becomes the standard by which other cultures measure themselves.

Critics of globalization suggest that globalization is a self-propelling social dynamic; others argue this is not true. In reality, the economic sphere is directed by the World Trade Organization (WTO) with its underlying goal of economic equality in political and cultural influence, through the powerful means of information technology, dominated by the West. The weak cultures may not be able to resist forces of globalization, but third world countries should not be unaware of the “hidden agenda” of globalization. It is argued that the transnational class of elite export a set of values consistent with the American ideology of liberalism and capitalism.

This view argues that globalization is a new form of activity in which a society moves from industrial capitalism to a postindustrial idea of economic relationships. This change is driven by a revolution among the techno-industrial elite that will eventually consolidate into a single global market. Recently, the information technology revolution has opened up new possibilities of communications and monitoring abilities across long distances, and has made it easier for transnational corporations to outsource some parts of their business.

There is a widening structural differentiation of goods and services that have spread influence across traditional political borders and economic sectors, and it has resulted in the greater influence of political and economic changes. These changes have transnational and multinational dynamics that are a major influence on outcomes in determining “issue-areas” (for instance, environment, trade, and world regulation) and

may encourage global and local companies to be more autonomous from a traditionally exclusive government decision-making and policy. Globalization can also be considered as the result of a larger building process of the world market.

Nevertheless, globalization is neither uniform nor homogeneous. There is a marked difference between the degree of globalization as reflected in trade, foreign direct investment (FDI), and international finance. Its boundaries are unclear and its constituent elements and multidimensional character have yet to be adequately explored. Some scientists have considered globalization as a first step to complex interdependence, which accepts the notion of transnational interpenetration. Other experts contend that globalization modifies deeply the structural framework of rational choice in world relations, since the role of the key factor that commonly defines both international and domestic relations (that is, the government) is subject to a critical structural transformation. The government commonly faces crises of both organizational efficiency toward the consumer and institutional legitimacy toward the citizen.

Therefore, there is a need to understand and propose new governance structures and mechanisms at the global and local levels, encompassing political and social needs of the government, social movements, non-governmental organizations (NGOs), grassroots movements, the media, transnationals, organized citizens, the science community, and religious movements.

### IMPORTANCE OF PLACE IN GLOBALIZATION

Historically, economic activity has been tied to geographic location. This relationship emerged around 1000 C.E., as political-military organization (empires, monarchies) absorbed autonomous cities that were the centers of economic activity in their geographic territory. The geographic merger of military and economic activities was transformed into a modern global interstate system that demarcates the physical boundaries of the world today.

To understand economic geography is to see the world as a mosaic of regions. Many researchers associate globalization with deterritorialization, where a variety of socioeconomic activities take place irrespective of the geographical location of the individuals or activities. One of the paradoxes addressed by researchers is why there has been a growth of dynamic local economies at a time when places are increasingly under the influence of, and threat of competition from, distant places—threats that are a consequence of the glob-

alization of the markets. One of the possible answers to this question is that local technological dynamism depends on local non-tradable assets such as trust or social capital. Does one refer to geography as preexisting spatial configurations that simply do not wither away in the midst of globalization processes? Or perhaps more significant, what is the explanatory relationship between geography and globalization? Is geography simply an outcome of globalization that poses as the cause? How does geography matter in our explanations of globalization? This last question points to a significant inversion of cause (geography) and outcome (globalization).

On the other hand, many of the contemporary views on trade theory and international economics predict that globalization will lead to more intra-industry specialization because of locational concentration. Territory, in the sense of a traditional sense of a geographically identifiable location, no longer constitutes the whole.

The rise of globalization seeks to capture the two-way interaction of global processes and local conditions to generate new adaptations. Globalization is associated with the production of new scales in economic and political space. It enhances the importance of supra-national and subnational scale processes. In particular, it underlies the arguments of a number of economic geographers that localized agglomerations of economic activity are a product of globalization. While this may be shown at the local level within the nation-state, it may also be argued at a more macro-level in such a regional formation as the EUROPEAN UNION (EU), seeking to define a "European identity" for its member states in a new global era. The hegemony of neo-liberal ideology is about the triumph of market-oriented ideology, the economization of life, mass consumption and entertainment, deregulation, and so on. It is a global ideological breakthrough in which democracy is considered to be a twin of the market economy, and these together are supported to form a winning team.

Frequently, it is theorized that economic globalization leads to deepening income inequality and unemployment. Similarly, debates on the winners and losers of economic globalization have also demonized globalization as a mythical juggernaut that is powerful enough to cause all sorts of socioeconomic miseries and political problems. More specifically, the intrinsic spatiality of economic globalization sets some necessary, but not sufficient, preconditions for it to effect empirical changes and outcomes. To define the spatiality of economic globalization, we have to look into

specific geographic foundations that presuppose and legitimize economic globalization: the transcendence and switchability of geographic scales and discursive practices as socio-spatial constructions. When coupled with other substantive political-economic forces, these geographic preconditions—not economic globalization *per se*—help to explain empirical consequences and outcomes.

Additionally, economic globalization represents a major transformation in the territory of key economic sectors. To what extent it also represents a possible transformation in the structures of politicoeconomic power is a difficult question. The major dynamics at work in the global economy contain the capacity to undo the interaction of sovereignty and territory embedded in the modern state system. This does not necessarily mean that sovereignty is less of a feature under conditions of globalization. Rather, it may signal the relocation of some components of state sovereignty onto supranational authorities. Similarly, economic globalization does not eliminate the government's exclusive control over its territory, but alters the particular type of institutional encasing of territory that has developed since World War II.

Globalization is the focus for popular fears about American power, the might of big business, the pace of economic change, and a sense of powerlessness in the face of intangible global forces. The debate is increasingly polarized between market fundamentalists and anticapitalists.

To satisfy short-term institutional investors and inflate the value of their share options, bosses gamble with their companies' future to ramp up the stock price. Unsurprisingly, trust in the financial system has evaporated since the collapse of Enron, Worldcom, Ahold, Parmalat, and others.

## CONCLUSION

The debate over globalization can be broken up into two main camps: the globalists and the skeptics. Globalists claim that globalization is a new transformation of world order and a positive change. They point to the interchanges between cultures, economies, and people. They herald the time-space compression as a seamless means for fixing many of the world's problems.

The skeptics, on the other hand, do not think that globalization is occurring, or if they do, they think it is a negative phenomenon. The skeptics also point to the growing size of state budgets, nationalism, and agreements between countries in regions, all processes that are regional, not global.

Globalization, as a myth, is the belief is that we are witnessing a process of regionalization with competing trade blocs. International economic integration has tended to be a regional rather than a global phenomenon. That is, the linkages among the world's economies have tended to be stronger, within defined geographic regions or blocs, than between those regions. Examples of these groups or blocs would include NAFTA (North American Free Trade Agreement), the EU, and Asian regional organizations. A regional pattern is clearly evident in the data on global trade flows. For the three regions cited above (which together account for about 80 percent of global gross domestic product), intra-regional trade in goods now accounts for 50 percent or more of exports. Also, it is clear that formal regional trade agreements such as NAFTA and the EU potentially foster intraregional trade.

Globalization versus localization suggests that distance matters, irrespective of transportation costs, so that spatial proximity of countries influences sales patterns over and above regional trade liberalization. It also seems clear that borders matter irrespective of distance. Globalization is sometimes credited with or blamed for influencing both domestic economic performance and the capacity of domestic policies to effect changes in that performance.

The power of national governments is reinforced, not weakened. The structural adjustments of the World Bank and IMF (International Monetary Fund), bilateral conditions, rationalization of existing structures, and new regimes under the WTO are factors that aid the globalization process. These processes are closing the policy choices for developing countries, which are losing their options. Developing countries are struggling to cope with the new conditions of development and survival. The process of globalization exacerbates the existing poverty and inequality situations within and among countries. Also, globalization is accompanied by the rising of inequalities within and between countries. Consequently, globalization can expose the internal problems and tensions among the states, societies, transnational corporations, and other global factors. The current agenda will be to delineate the path to achieve sustainable development and minimize the risks.

UNIVERSITY OF MONTPELLIER, FRANCE

## Gobi Desert

THE 650,000-square-mi (1,600,000-square-km) Gobi is the largest desert in CHINA and MONGOLIA; both the Taklamakan Desert (in XINJIANG) and the Changtang Desert (in TIBET and Qinghai) are only half the size. Only the SAHARA is bigger than the Gobi among the world's deserts. The Gobi separates the Republic of Mongolia from the province of Inner Mongolia in the People's Republic of China (PRC). In Mongolia, the Gobi occupies all the southern districts (*aimak*) of the country: eastern Gobi, central Gobi, southern Gobi, Baian Khongor, and Gobi Altai. In China, the Gobi Desert extends from Manchuria to Gansu and Xinjiang. It consists of several plateaus: Hulun Buir, Xilin Gol, and Ulanqab in the east and the Alashan plateau in the west of Inner Mongolia. The Yinshan Mountains and the Hexi corridor form the southern edge of the Gobi Desert.

Although vast, the Gobi peneplain is neither the driest nor the warmest desert in western China. The Siberian high-pressure system keeps the Gobi dry and very cold in winter; in summer, the monsoon winds bring a few inches of precipitation to the region. The meager vegetation and the brief growing season account for the barren appearance of the Gobi. Topographical profiles of Inner Mongolia display a succession of denuded hills covered with *gobi* pebbles and basins covered with sandy *gobi* gravel. *Gobi* or *govi* usually means "desert" in Mongol, although an absolute desert would be

called *tjall* or “waste.” *Gobi* designates also the wind-eroded small basins that are scattered in the desert. Chinese geographers establish a difference between sandy desert (*shamo*) and gravel desert (*gobi*). They call *gobi* the gray surface of hard pebbles that covers dilluvial plains. Sand dunes are indeed rare in the Gobi Desert.

### FORMIDABLE PROTECTION

The Gobi enjoyed a semitropical climate during the Cretaceous period (145 to 160 million years ago). The paleontologist Roy Chapman Andrews organized, in the 1920s, the Central Asiatic expeditions of the American Museum of Natural History. He discovered rich repositories of dinosaur fossils in what is now a forbidding desert, with badlands and salt flats. The two characters in Chinese to transcribe *Gobi* are *ge*, “halberd,” and *bi*, “wall.” Combined, they suggest that this type of desert constitutes either a dangerous obstacle or a formidable protection. No major road crosses the Gobi Desert except for the imperial highway from Kalgan (Zhangjiakou) to Ulaanbator and the much more recent Transmongolian railway that links Beijing and Ulaanbator via Baotou. The Gobi plays today an unexpected role in space-based international communications as the launch site for Chinese Long March rockets; the Jiuquan launch site lies in the western Gobi Desert (Gansu province).

## Golan Heights

THE GOLAN HEIGHTS (in Arabic, Al-Jaw-lan) is a hilly region in southwest SYRIA, bordering nearby regions of LEBANON and JORDAN, with a highest point of 7,297 ft (2,224 m). The area is one of the most heavily disputed areas in the history of the 20th century. When the state of ISRAEL emerged after the vote of the United Nations and the war of independence in 1948, the Golan Heights, under Syrian rule, were used as a military tactical point against Israel. Up to the war of

The Golan Heights (above, pre-1967) remain a hotspot of international tension between Israel and Syria.

1967, Syria used the Golan Heights to attack Israeli villages from the Sea of Galilee to the Lebanese border with sporadic artillery fire. The Golan Heights were heavily fortified by the Syrians, but the Israelis were informed about these activities by their master spy, Elie Cohen. The Israelis were able to take the Golan Heights in little more than 24 hours during the 1967 war, and the Syrians lost their decisive strategic asset for shelling large parts of northern Israel.

In the war of 1973, the Israelis were taken by surprise, including on the Syrian front. After heavy losses, the Israelis, in an unprecedented turn of the tide, drove out the conquering Syrians and were only stopped by political pressures from the UNITED STATES to go all the

way to DAMASCUS, the Syrian capital. After political negotiations brokered by U.S. Secretary of State Henry Kissinger, Israel and Syria signed a disengagement agreement in 1974. The Israelis gave back the Syrian land conquered in 1973 and even part of the Golan Heights area (especially the city of Kuneitra).

The economic importance of the Golan Heights is negligible (apart from some tourism, including winter sport facilities in the Mount Hermon area), but the strategic importance of the Golan Heights is gigantic. By its prominent position, the Golan Heights can control many parts of northern Israel. Therefore, the Israeli parliament made the Golan Heights part of Israel in 1981. U.S.-brokered negotiations in the 1990s for a peace settlement between Syria and Israel failed, as the Syrian side demanded the return of the Golan Heights before any peace settlement, and the Israeli side ruled out discussions on a change of sovereignty of this strategic asset without any durable peace settlement with Syria. The Golan Heights remain a hotspot of international tension and could well become the setting for another war, although the area has limited immediate military presence as a consequence of the agreements of the 1970s.

## Grand Canal (China)

THE GRAND CANAL is one of the wonders of the world. Built in the 7th century by CHINA's Sui Dynasty, it stretches about 1,100 mi (1,800 km) across eastern China—about the same distance as MIAMI, FLORIDA, to NEW YORK CITY, or LOS ANGELES, CALIFORNIA, to Vancouver, CANADA. The canal was built to transport rice and silk from the rich and fertile south to the dry and barren north, particularly to soldiers protecting the frontier and the northern capital, BEIJING. Major cities grew up along its route, which remain major commercial centers to this day, although much of the canal is now too small or too full of silt to carry major boat traffic.

The Grand Canal, Da Yunhe in Mandarin Chinese, has been called the “Bridle on the Dragons” since it crossed China's five major east-west rivers and helped control perennial flooding in the region. Throughout China's history, dynasties could rise and fall depending on their ability to control these floods; natural catastrophe was a sign of displeasure from the heavens and frequently led to change in regime. Sections of the canal were built as early as the 4th century B.C.E., though most of it was undertaken in the 7th century C.E. by the notoriously cruel Emperor Yangdi: The forced labor of millions of peasants accomplished a nearly complete canal in only six years. It linked the southern city of Hangzhou to Xi'an (then the largest city in the world), and from there trade passed overland via the SILK ROAD to western Asia and Europe. The canal still begins at Hangzhou, capital of the 13th-century Song Dynasty, which was visited by Marco Polo, who described it as the most magnificent city in the world. When the Mongols (Yuan Dynasty) set up a new capital at Beijing in the next century, the canal was extended further north to feed the capital and its armies with rice from the south.

Heading north from its terminus at Hangzhou, the Grand Canal crosses the provinces of Zhejiang and Jiangsu, where it passes through the city of Suzhou, sister to Hangzhou. Both cities are famous for their gardens and natural beauty (Suzhou is sometimes referred to as the “Venice of the East” because of its extensive canals). The canal forms the main street for commercial cities like Wuxi and Xuzhou, where hundreds of small junks compete for space with larger barges, loading and unloading products—silks, rice, green tea—onto train lines that reach far into the Chinese interior. The canal then intersects the Changjiang (Yangzi River) about the midpoint between two of China's most important cities, Shanghai and Nanjing. Following the contours of the North China Plain, the canal is at its deepest and widest, enough for 600-ton riverboats.

Small rice plots surround the canal for miles. The landscape begins to change as the waterway enters Shandong Province: plaster and tile houses of the south give way to mud and thatch in the north, wheat replaces rice as the dominant crop, and mules replace water buffalo as the major domesticated animal. This region is heavily affected by drought and floods, and much of the region's trade has shifted to railroads, leaving many sections of the canal completely dry, with much of its water used for irrigation. The canal no longer enters the Huang (Yellow) River, which has

risen about 20 ft (6 m) on silt deposits, kept in by dikes. From the Huang River, the canal works its way north through Hebei Province to Tianjin, the port city for Beijing. Formerly connecting Beijing to its port, the canal is now unnavigable between the two cities.

## Grand Canyon

WITH DIMENSIONS of 277 mi (446 km) long and 18 mi (29 km) wide, the Grand Canyon is one of the most spectacular natural wonders of the world. Crafted by the Colorado River, it is an enduring and unchallenged natural symbol of North America. At its present size of 1,904 square mi (4,911 square km), the Grand Canyon is the fourth-largest park in the lower 48 states of the UNITED STATES.

Formation of the canyon is a relatively recent event, in geologic time. The Grand Canyon is a vast landscape composed of layers upon layers of different kinds of rock that are distinct in color and texture. Basement rocks of black Vishnu schist, hard metamorphic rock, and granite form the inner gorge of the canyon. The Kaibab limestone found on the canyon crest is estimated to be 225 million years old.

River runoffs from the rims have cut hundreds of side canyons, which spread and gradually isolated the buttes and mesas that now tower thousands of feet above the canyon floor. Half of the Earth's history is represented in the rocks at the Grand Canyon. On its walls, four geologic eras are visible in the sedimentary rocks. The fossils in its layers illustrate the evolution of life: Nowhere else in the world has been found a clearer view of geologic processes.

Climate at the canyon varies with the season and altitude. The North Rim, which is 8,000 ft (2,438 m) above sea level, receives so much snow that access by road is cut off to tourists all winter (late October to early May). Between June and August, normal daytime temperatures at the rim rise above 70 degrees F (21 degrees C), while nights remain somewhat cool. The

South Rim, at 7,000 ft (2,134 m) above sea level, is open year-round. At night, the temperature still drops well below freezing between late October and April. Upper portions of hiking trails get dangerously icy. Between May and September daytime temperatures will have highs above 70 degrees F (21 degrees C) at the rim; no matter what the season, it is always much warmer at the bottom of the canyon.

The temperatures in the Inner Canyon, at river level—almost 5,000 feet (1,524 m) below the South Rim—are often in excess of 100 degrees F (38 degrees C) on most days between late May and early September. The temperature at the river is unlikely to drop below 70 degrees F (21 degree C) even at night. Little direct sun reaches the bottom of the canyon, but the bottom of the canyon seldom freezes, and December highs remain well over 50 degrees F (10 degrees C).

Precipitation in the canyon is fairly rare, except for some snow in winter and rain in August, when afternoon thunderstorms sweep in and blow over quite rapidly. The canyon receives 15 in (38 cm) of rainfall in an average year, and at any time during the year the canyon can be invisible beneath a layer of cloud or fog. Despite the fact that Grand Canyon boasts some of the cleanest air in the United States, air pollution from far-away cities, smelters, and neighboring power plants continues to reduce visibility at the Grand Canyon by 30 percent below natural levels. In September 2001, the owners of the Navajo Generating Station made an agreement with the Grand Canyon Trust to reduce sulfur emissions by 90 percent.

The Grand Canyon receives nearly 5 million visitors annually. Thirty percent are foreign tourists. Most come to the South Rim, stay only for a few hours, and use the many observation points to look across and down into the canyon. But to truly experience the Grand Canyon, one must go down in it. To get inside the canyon, tourists can hike down preserved trails or take a mule ride to the bottom of the canyon. Rafting whitewater rapids through the Colorado River is another way to experience the massiveness of the Grand Canyon from within. There are also several campsites inside the canyon for adventurers seeking to enjoy more than a few hours of the experience.

Cascading waterfalls plunge into waiting pools of water on the Havasupai Indian reservation, near the lower end of the canyon. The canyon was home to at least seven Native American tribes, and the Hopi Indians still regard the canyon as their place of emergence onto the Earth and the place where their dead return. Their predecessors left behind more than 3,000 archae-

ological sites and artifacts as old as 10,000 years. Home to 88 species of mammals and 315 species of birds, the Grand Canyon was declared a national monument in 1908, when President Theodore Roosevelt decided to protect it in perpetuity; in 1919 the U.S. Congress authorized the expansion and upgrading of the monument to a national park.

## grasslands

MANY DIFFERENT TYPES of ecosystems throughout the world are described as grasslands because they are dominated by species of grass with a range of other plant types as subordinates within the community. Grasslands occur at most latitudes and altitudes reflecting the wide range of environmental tolerances that characterize this huge taxonomic group of plants known as the *Gramineae*.

There are approximately 9,000 species within this group. They are described as monocotyledons because there is only one leaf protecting the seed, in contrast to most flowering plants, which have two seed leaves and are known as dicotyledons. Grasses reproduce by generating and dispersing seed; many species spread through the production of underground stems called tillers. These two characteristics have been widely exploited in agricultural systems. First, many species producing particularly carbohydrate-rich seeds have been domesticated, a process begun more than 10,000 years ago, and today they are major cereal crops of arable agriculture, notably rice, maize (corn), wheat, barley, oats, rye, and sorghum. Second, the ability of grasses to produce a turf ground cover through tillering and the placement of the growing points close to the ground facilitates grazing by herbivorous animals and thus underpins pastoral agriculture worldwide.

Broadly, grasslands may be classified as natural, seminatural, and artificial. Each of these groups can be

further subdivided. Natural grasslands are widespread and tend to occur where climatic or soil conditions prohibit the growth of shrubs and trees; annual precipitation regimes are especially influential, as a pronounced dry season or seasons is characteristic of grasslands, along with a low annual precipitation. The occurrence of natural fire may have also played a role in the formation of continental grasslands. Other factors may give rise to grasslands locally, such as persistently cold, high-speed or salt-loaded winds in coastal areas.

### GRASSLAND CATEGORIES

The main categories of natural grasslands are alpine or high mountain grasslands; high-latitude TUNDRA; temperate grasslands such as the prairies of North America; the PAMPAS of South America; the STEPPES of Eurasia; the grassveld of the high PLATEAUS of SOUTH AFRICA; and tropical grasslands such as those of savanna regions. Most are in continental interiors with moist continental or dry subtropical climates. All of these grasslands can be further subdivided. The prairies, for example, comprise the eastern and western prairies that are separated by the ROCKY MOUNTAINS. Moreover, the eastern prairies comprise three communities: tall-grass, mixed-grass, and short-grass prairies, which reflect decreasing precipitation along an east to west gradient. A similar gradation exists in the steppes, where tall-grass communities are known as meadow and short-grass communities as typical steppe. Savanna, by definition, is a vegetation type in which grasses form a continuous ground cover.

However, there may also be trees and shrubs present in various degrees from sparse to abundant. All of these grasslands have been considerably modified by human activity, especially for arable and pastoral agriculture. Indeed, the prairies and steppes are considered to be the "bread basket" of the world because of their production of wheat. Alpine grasslands are exploited for summer feed for animals, for example, yak production in MONGOLIA and cattle production in SWITZERLAND, in a practice known as TRANSHUMANCE.

Seminatural grasslands occur in areas once occupied by trees and shrubs and where some type of human activity has favored the spread of grasses. Grazing and forestry are the most significant causes of this shift. Grazing prohibits the growth of trees and shrubs, as they are eaten by animals, while favoring grasses that can withstand grazing pressure. Forestry, once land has been cleared of trees either in small patches or through clear felling, generates unshaded conditions

avored by grasses. Controlled firing may be a significant component of such management strategies. Consequently, seminatural grasslands exist throughout the world in areas that could and once did support a forest cover. They vary in size from small glades to many hectares and the grass species present reflect local climate and soils as well as the plant community composition of the source areas from which the invaders derived.

Artificial grasslands are so called because they occur in areas that could support trees and shrubs but these are prevented from growing through management. Their floristic composition is manipulated through seeding and dressing with fertilizers and herbicides that favor species with high nutritional value for grazing animals. Such grasslands are common in countries where high-technology agriculture is practiced, especially in the developed world.

## Great Barrier Reef

THE GREAT BARRIER REEF, located on the northeast coast of AUSTRALIA, is comprised of the world's largest cluster of coral reefs. It is 1,250 mi (2,012 km) long; running along 10 mi (16 km) of the eastern Australia shore in the north to 100 mi (161 km) in the south. Its length is comparable to that of the entire West Coast of the continental UNITED STATES.

The Great Barrier Reef is an example of the key stages in the Earth's continuing ecological and biological evolution of natural phenomena and habitats. The Great Barrier Reef's diversity shows the development of an ECOSYSTEM that has evolved over hundreds of thousands of years. It is the world's most extensive coral reef system and is one of the world's richest areas in terms of plant and animal uniqueness. There is more than just coral to the Great Barrier Reef. It also contains widespread areas of sea grass, mangrove, soft bottom, and island communities. The reef is not a con-

tinuous barrier, but a broken maze of coral reefs and cays (ledges). There are approximately 2,800 individual reefs, of which 760 are fringing reefs that form against or near an island or continental coast and grows seaward, sloping sharply toward the seafloor.

The Great Barrier Reef provides habitats for abundant forms of marine life. The reef is the largest structure ever built by living creatures, and consists of thousands of separate reefs, islets, and islands. The reef contains approximately 1,500 species of fish, 400 species of sponges, 4,000 different types of mollusks, and approximately 400 species of hard, reef-building corals. The coral is a growth of calcareous (calcium or calcium carbonate) remains accumulated over a period of some 25 million years. The marine life of the warm, clear waters of the reef is plentiful and varied, consisting of anemones, marine worms, gastropods, crayfish, lobsters, prawns, crabs, starfish, sea urchins, and a great variety of fish and seabirds. Among the better known species are the crown-of-thorns starfish (*Acanthaster*), the giant clam (*Tridacna gigas*) the deadly box jelly, sea wasps, and many brightly colored fishes.

The reef also supports a wide variety of fleshy algae that are eaten by the resident turtles, fish, sea urchins, and mollusks. The reef is the habitat of such endangered species as the dugong sea cow and the large green loggerhead turtle. The reef sea-grass beds are an important feeding ground for the dugong and are a nesting ground for the loggerhead turtles. It is also a breeding area for humpback whales, which come from the Antarctic to give birth to their young in the warm waters. The islands and cays support several hundred bird species, many of which have breeding colonies there. Reef herons, osprey, pelicans, frigate birds, sea eagles, and shearwaters are among the numerous sea birds that have been recorded.

The Great Barrier Reef Marine Park was acknowledged in 1975 with the purpose of preserving the area's outstanding biodiversity while allowing reasonable use for local economy through zoning laws. The environmental risks related to shipping within the Great Barrier Reef are operational pollutants and accidental pollutants, the major threat being from oil, either carried as fuel or cargo.

There are over 30 historic shipwrecks in the area, as well as a scattering of islands ruins, operating and historically significant lighthouses, and World War II sites. Captain James Cook is believed to have been the first European to encounter the reef when his ship the *Endeavour* ran aground on it in 1770 near what is now Cooktown. Human involvement with the Great Barrier

Reef began thousands of years before Captain James Cook encountered the reef. Aboriginal peoples and Torres Strait Islander communities have fished, hunted, and gathered from its waters, islands, and adjacent coastal areas for thousands of years. These people have significant traditional cultural connections to the Great Barrier Reef. The many important cultural sites that are evidence of past and in some cases contemporary activity are one aspect of their living cultural heritage that exists across the islands and reefs in the Great Barrier Reef Region. The hunting of marine animals such as dugongs and turtles has long been part of Aboriginal culture, and these activities continue as part of the cultural heritage. Chinese fisherman and Japanese pearl divers also frequented the waters of the reef in the 19th and early 20th centuries.

## great circle

A GREAT CIRCLE IS defined as a direction line that forms a full circle. This is also called a true azimuth. A great circle divides the Earth into equal halves and on the idealized surface of the Earth, the shortest distance between two points lies along a great circle. The equator is a great circle, as are all meridians of longitude. A great circle has a number of considerable properties. It is the largest possible circle on the globe, and every great circle has its center in the center of the Earth and its circumference is the circumference of the Earth.

One of the most important uses of great circle distances is by navigators of ships and aircraft. Measuring and determining direction is different between that on the spherical earth and that of flat surface direction finding. Traveling along a great circle (called the great circle route) is the shortest distance between two places on the Earth. Air and sea transportation lines tend to use great circle routes as much as possible to save on travel time and costs. Finding distances between points on a great circle is accomplished using the known lati-

tude and longitude of the two points and using trigonometric tables.

Users of the great circle route need to select the proper map PROJECTION to display properly a great circle route. Maps distort distances so the great circle route may appear longer than a straight line on a flat map. The only map projection that portrays great circles as straight lines is the gnomonic projection. The drawback to using this projection, however, is that they cannot illustrate a whole hemisphere in one map. Other azimuthal projections are sometimes useful for navigators looking at great circle routes because of their symmetrical nature, making all great circle routes passing through their centers appear as straight lines.

Another challenge appears when plotting a course using a great circle route. Compass direction along a great circle route varies constantly. To avoid constantly having to check and recalculate compass direction, followers of great circle routes can lighten their burden by following what is called a constant azimuth path. The difference between a true azimuth path and a constant azimuth path is that the true azimuth path is the shortest distance between two points on the surface of a globe and the constant azimuth path is the path followed by using a constant compass heading.

## Greece

**Map Page** 1133 **Area** 51,012 square mi (130,800 square km) **Capital** Athens **Population** 10,665,989 **Highest Point** 9,626 ft (2,917 m) **Lowest Point** 0 m **GDP per capita** \$19,000 **Primary Natural Resources** bauxite, lignite, magnesite, petroleum.

FOR OVER 4,000 years, Greece has been at the crossroads of civilizations. The great empires of the Western and Eastern worlds met, clashed, and exchanged ideas

here. The ancient Greeks contributed to the development of European civilization in many ways, most notably in the areas of philosophy and politics. Shaped by their country's lengthy coastline and rocky inhospitable interior, the Greek culture has always been dominated by the sea, as much for the ancients as it is today. Modern Greece is bordered to the northwest by ALBANIA, to the north by the Former Yugoslav Republic of MACEDONIA (FYROM) and BULGARIA, and to the east by the AEGEAN SEA and TURKEY. To the west lie the Ionian Sea and ITALY. Like Italy, Greece comprises a peninsula that protrudes into the MEDITERRANEAN SEA.

Greece is known officially as the Hellenic Republic, taking its name from the classical Greeks' name for themselves, the Hellenes. At its height in the 5th century B.C.E., Classical Greek, or Hellenistic, civilization stretched from the western Mediterranean (Marseilles, FRANCE, was originally a Greek city) to the INDUS RIVER. Eclipsed by the rising Roman Empire in the 2nd century B.C.E., Greece reemerged as the center of the Mediterranean world with the founding of the city of Constantinople in 330 C.E., and the establishment of the Byzantine Empire. Byzantium slowly lost ground to the Ottoman Turks over several centuries, finally succumbing to conquest in 1453. For 400 years, Greeks struggled to maintain their identity as a people within the OTTOMAN EMPIRE, until a successful revolt in 1829 reestablished an independent kingdom of Greece, which, over the next 60 years, gradually extended its boundaries to incorporate the rest of the Greek peninsula and the islands of the Aegean Sea.

This expansion was halted after a disastrous war with Turkey in 1922, which resulted in the deaths or forced migrations of millions of Greeks from Asia Minor and Anatolia. Lingering tensions between the two nations are not helped by the fact that many Greeks would like to see such quintessentially Greek cities as Smyrna, Ephesus, and especially Constantinople itself (modern ISTANBUL) returned to the fold. Pressure exerted by the NORTH ATLANTIC TREATY ORGANIZATION (NATO) and the EUROPEAN UNION (EU), however, has worked to end this conflict that has spanned a millennium.

Greece joined NATO in 1952, became a parliamentary republic by removing its king in 1974, and joined the European Community (forerunner of the EU) in 1981. Although cut off geographically from the other nations of the EU, it remains a solid outpost of European development in Europe's southeast, and a strategic NATO partner at the doorstep of the MIDDLE EAST.

The modern nation of Greece consists mainly of the southern end of the Balkan Peninsula, and over 2,000 islands. A highly indented coastline stretches for over 8,400 mi (13,600 km). About 200 of the islands are inhabited, including the largest (and the fifth-largest in the Mediterranean), Crete. Greece's second largest island, Euboea, nearly forms part of the mainland, running parallel to the Attic Peninsula for roughly 900 mi (1,500 km). Other major islands in the Aegean include Rhodes, Cythera, Naxos, Samos, Chios, Lesbos, and Lemnos, plus the island groups of the Cyclades, Sporades, and the Dodecanese. To the west of the peninsula lies the Ionian Sea, in which are even more islands: the Ionian Islands (Cephalonia, Zante and Ithaca) and Corfu. Many of these islands are important wintering grounds for migratory birds.

The southernmost part of the Greek peninsula is nearly an island itself, the Peloponnesus, connected only by the narrow Isthmus of Corinth. This area was the site of powerful ancient city-states such as Mycenae and Sparta and the birthplace of the Olympic Games. Immediately to the northeast is the Attic peninsula, where the majority of the Greek population lives, in and around the city of Athens (Athinaí, with a metropolitan population of 5 million, or 40 percent of the total population). Attica is also the site of many of Greece's most ancient monuments, the city of Thebes, the oracle at Delphi, and several of the major battlefields of the ancient world, including the famous battle of Marathon, in 490 B.C.E., in which the Greeks defended their independence against the largest imperial power of the day, the Persian Empire. Greece's second largest city, Salonica (Thessaloníki), is much further to the north, and is the capital of the province of Macedonia, a major port and industrial center. Macedonia includes the third major peninsula on mainland Greece, Chalcidice (Khalkidhiki), with its famous Orthodox monastery of Mount Athos, which has been allowed to rule itself autonomously for centuries.

Because it is made up of so many mountainous peninsulas jutting out into the sea, Greece has only a few rivers over 62 mi (100 km) in length. The longest of these, the Aliákmon, is only 184 mi (297 km) long. This river, and the Piniós to the south, are the primary rivers that drain the plains of Greece's north-central regions (Macedonia and Thessaly). Greece has very few lakes, but there are three of significant size, one in each corner of Greece: Trikhonís in the southwest, Voivíis in the east, and Vegorrítis in the far north. The spine that runs down the center of the main Greek peninsula is the Pindus Mountain range. These stretch from the

highland province of Epirus in the northwest, down to Attica and across to the Peloponnesus in the south. A second mountain chain, the Rhodope Mountains, runs along Greece's northern border with FYROM and Bulgaria. The highest mountain in Greece, however, is not a part of either of these chains. Mount Olympus, reputed to be the home of the gods in Greek mythology, stands alone above the plain of Thessaly.

Thessaly forms one of the few places in Greece where the terrain is level enough to permit agriculture on a larger scale. The rest of Greece consists mostly of sharp, rocky hills, with a dry and temperate climate year-round, sufficient only for the cultivation of olives, grapes and goat's cheese, Greece's primary exports. Lacking rich farmland, the Greeks thus turned to the sea for their primary livelihood. Today, the Greek merchant fleet is the largest in the world (excluding non-nationally owned fleets, such as the multinational registries of LIBERIA or PANAMA). It is estimated that one family in 11 in Greece is connected in some way to the shipping industry and that Greek shipping accounts for 70 percent of all EU maritime commerce.

Other significant industries include tourism, especially with the exposure from the 2004 Olympic Games in Athens. Natural resources include bauxite (aluminum ore) and alternative power sources, including hydropower, geothermal, and solar energy, fueled by Greece's ever-present sunshine. There are estimated oil reserves in the eastern Aegean, but these have largely gone untapped because of yet another conflict with Turkey over how far each nation's boundary extends over the continental shelf.

Turkey is not the only nation that has disputes with Greece. Albania contests the borders of Epirus, claiming large numbers of ethnic Albanians living inside Greek borders, which official Greek statistics do not show. The Former Yugoslav Republic of Macedonia has been denied the use of its name "Macedonia" and its flag, the ancient symbol of Alexander the Great, since its independence in 1991. Although Greece dropped its economic blockade in 1995 (and allowed FYROM to take a seat at the United Nations), it continues to insist that the Slavic country drop its Hellenistic name and symbols.

Greece also firmly supports the claims of its Greek brethren to the entire island of CYPRUS, fanning the flames of continued ethnic strife with the Turks in northern Cyprus. Greece's far northeastern province, Thrace, where roughly 1.5 percent of the population are Turkish Muslims, is, by contrast, quite peaceful. A Greek-Turkish partnership in NATO, and potentially

in the EU, was furthered by the twin natural disasters of 1999. Rescue efforts from both nations were quick to come to the aid of victims of earthquakes only three weeks apart, leaving an impression of goodwill that bodes well for future regional cooperation.

## Greenland

ONE OF THE MOST northerly territories in the world is Greenland, located between the North ATLANTIC, the northeastern coasts of CANADA (Ellesmere and Baffin islands), and the ARCTIC OCEAN. More than two-thirds of the region lies above the ARCTIC CIRCLE. Greenland is technically considered part of North America, though ICELAND (usually considered part of Europe) lies only 186 mi (300 km) to the southeast. Greenland is the world's largest island that is not considered a continent (like AUSTRALIA). It is roughly one-third the size of the UNITED STATES, and 50 times the size of its parent nation, DENMARK. Greenland has been a part of Denmark for centuries, officially integrated within the kingdom in 1953, but has had internal self-rule since 1978.

A victim (or beneficiary) of early Viking propaganda to encourage new settlements, Greenland is in fact mostly ice. The island consists almost entirely of a vast inland plateau covered in ice up to 9,800 ft (3,000 m) thick. It is estimated that this ice sheet, second in size only to ANTARCTICA, holds up to 10 percent of the world's frozen water.

The interior plateau is surrounded on all sides by mountains, the highest being those along the east coast (including Greenland's highest point, Gunnbjørn). A narrow coastal plain supports most of the settlements, mostly along the south-west coast. Here there is a short summer growing season, but, as in most of the rest of the island, the chief industry is fishing. Other economic activities include the hunting of whales and seals and, to some extent, tourism. Adventurous tourists are drawn to the rugged subarctic terrain and the dramatic

ice fjords but primarily to the celestial attractions: the northern lights and the midnight sun. North of the Arctic Circle, the sun never sets between late May and late July. The town of Ilulissat (Jakobshavn) is one of Greenland's tourism centers, both for the midnight sun and for its position among dramatic glaciers and icebergs that flow into Disko Bay. In contrast to the summer, however, most of these northern settlements see no sunlight at all from November to January. The east coast of Greenland is almost entirely uninhabited and has mostly been isolated from European contact.

Greenland's official name, Kalaallit Nunaat, means "land of the people." Most of its population are Inuits, closely related by language and culture to Canadian Inuits and Alaskan Eskimos. Migrations from North America occurred as recently as 150 years ago. Many traditional Inuit practices continue today, such as the use of kayaks in hunting (the word *qajaq* is Inuit), and the crafting of *tupilaks*, small grotesque figures carved in walrus tusk or reindeer antler to represent evil spirits. Europeans first arrived in southern Greenland around the year 1000, under the leadership of the Norwegian (Viking) chieftain Erik the Red.

By the early 15th century, however, these settlements were abandoned. English navigators charted the island again in the late 16th century, in the process of searching for the Northwest Passage to the Pacific. Danish and Icelandic settlers gradually established small fishing villages on the southwest coast, but it was not until 1921 that Denmark declared the entire island to be Danish territory, following the 1917 treaty by which Denmark sold the Virgin Islands to the United States, and in exchange, the United States relinquished its claims to the northern parts of Greenland.

Greenland has been developed economically only since the 1950s, as Denmark made strides to integrate Greenlanders more fully into the kingdom. There are still no roads between settlements, however, and attempts to commercially mine minerals beneath the interior ice cover (primarily zinc and lead) have been slow to develop. There is also potential for large deposits of uranium and oil, but these remain mostly unexplored. The population continues to rely heavily on subsidies from Denmark (nearly \$200 million a year). A 1978 referendum brought self-rule, and through a further vote in 1985, Greenlanders chose to leave the markets of the European Union after many years of haggling over fishing and mining rights.

The capital city, Nuuk (Godthåb, Danish for "the headland"), is a very modern city, built mostly since the 1950s, and housing over 13,000 people, three times

the population of the second-largest town. Rapid modernization has, however, taken a toll, and the city is marked with high unemployment, alcoholism, and teen suicide.

## Grenada

**Map Page** 1137 **Area** 133 square mi (344 square km)  
**Population** 89,258 **Capital** Saint George's **Highest Point** 2,756 ft (840 m) **Lowest Point** 0 m **GDP per capita** \$5,000 **Primary Natural Resources** timber, tropical fruit, agricultural products.

GRENADA IS AN independent island country in the CARIBBEAN SEA. It is a member of the British Commonwealth. The country was in the news in 1983, when the UNITED STATES led a successful military invasion of the island to protect U.S. citizens there and to restore the island's parliamentary form of government. Free elections have taken place there ever since.

Grenada is one of the smallest nations in the Western Hemisphere; it is about twice the size of Washington, D.C. The country consists of the main island of Grenada, which makes up three-fourths of the country's total land area, as well as hundreds of mostly uninhabited tropical islets. Three landscapes divide the main island: a coral-lined shore, an agricultural plain fringed by mangrove swamps, and a mist-shrouded volcanic highland. Tropical storms and hurricanes traveling from the Atlantic Ocean menace the islands each year. Volcanic eruptions also threaten the tiny nation: A volcano (Mount St. Catherine) dominates the main island of Grenada and a submarine volcano (Kick-Em-Jenny), which is the most active volcano in the Windward Islands region, rumbles fitfully 5 mi (8 km) offshore. The climate is the tropical-wet type.

Temperatures average a sweltering 84 degrees F (29 degrees C) throughout the year. Northeast-flowing trade winds assure abundant moisture from June through November, when the Intertropical Convergence Zone (ITCZ) passes over the islands. Precipitation decreases noticeably when the ITCZ shifts south during the remainder of the year. Due to the prevalence of the northeast trade winds, there is a prominent rain shadow area on the leeward (southwest) side of Mount St. Catherine.

All but about 700 of the country's population lives on the main island of Granada. Approximately 82 percent of the people are black, 13 percent mixed black and European, and 5 percent European and East Indian. The only large urban center is the capital, St. George's (population 4,300). English is the official language, but most people also speak French patois. The main island's impressive production of nutmeg, cinnamon, ginger and cloves earns it the nickname Spice Island. Bananas, cocoa, citrus, avocados, sugar cane and root crops also earn income. Industry involves agricultural processing, construction, offshore financing, and tourism. Grenada was the world's second-poorest country based on the percentage of the population living below the poverty line in 2003. (DOMINICA, which is also a Caribbean nation, ranked first.)

## grid/graticule

THE EARTH IS NOT spherical but rather an ellipsoidal shape where the north and south poles are flattened and the equator bulges. This unique shape is called a geoid. In order to uniquely locate features on the Earth's surface, a reference system is required. An imaginary network of lines called a grid or graticule is superimposed on the Earth to serve this purpose.

Although the terms *grid* and *graticule* are used synonymously, there is a subtle technical difference in their meaning. A graticule is a referencing system tied directly to the Earth's ellipsoidal shape. On the other hand, a grid is a network of perpendicular lines, much like graph paper, superimposed on a flat paper map to

provide relative referencing from some fixed point as origin.

The graticule is composed of longitude lines (meridians), which run north-south, and LATITUDE lines (parallels), which run east-west. The longitude lines converge at the North Pole in the Northern Hemisphere, and at the South Pole in the Southern Hemisphere. The equator divides the Earth into two hemispheres. All meridians and the equator are great circles since they can form planes that cut the surface and pass through the center of the Earth. Small circles such as latitude lines form a plane that cuts the surface but does not pass through the center of the Earth. In this system of reference, geographic coordinates are measured in units of angular degrees.

There are 360 degrees of longitude around the equator, with each meridian numbered from 0 to 180 degrees east and west such that the 180 degree meridian is on the opposite side of the Earth from Greenwich, England. There are 180 degrees of latitude from pole to pole, with the equator being 0 degrees and the north and south poles being 90 degrees. Each degree is divided into 60 minutes (60') and each minute is divided into 60 seconds (60"). The north-south line is called the prime meridian, which has been arbitrarily set to pass through the Royal Observatory in Greenwich, England. The longitude is measured as the angle between the point, the center of the Earth, and the prime meridian at the same latitude. West is positive and east is negative, meeting at 180 degrees at the international dateline. The east-west line follows the equator and is midway between the north and south poles. Degrees of latitude are measured as the angle between the point on the surface, the center of the Earth, and a point on the equator at the same longitude. In this graticule reference system, the size of the cells is largest at the equator and the zones are square. At the poles, the zones are smallest and triangular.

When the three-dimensional Earth is projected unto a flat paper map there are distortions in distance, area, and direction, and the projection process attempts to minimize these distortions when transferring the curved Earth to the flat map. The projection process affects both the graticule and Earth features. On the flat map there is no natural reference point, but one can be defined using an arbitrary system of coordinates. A grid of intersecting parallel and perpendicular lines is placed over the projected map such that the origin of the grid lines fall on a point of interest on the map. This arrangement is called a grid reference system, and every point on the flat map can be located

with a unique X and Y coordinate. Usually, the X coordinates are referred to as eastings and the Y coordinate as northings. An example of a grid system is the Universal Transverse Mercator (UTM) system.

Graticules are always expressed in geographic coordinates (latitude and longitude) while grids are expressed in some locally defined X and Y coordinate system. In projected coordinate systems, graticules will appear as curved lines (when necessary) to follow the curved form of the meridians of longitude or parallels of latitude in the projection. Grids, however, will always appear as an arrangement of horizontal and vertical straight lines.

## growth pole

GROWTH POLE REFERS to the concentration of highly innovative and technically advanced industries that stimulate economic development in linked businesses and industries. This concept was first introduced by François Perroux in 1950, was further sharpened in following publications, and finally evolved into an idea that came to take on a meaning rather different from the one posited by Perroux. While he had conceived a growth pole to be a focus of economic development in an abstract economic space, it was interpreted by his disciples, particularly Jacques Boudeville, to be a focus of development in geographic space.

Perroux, a 20th-century French economist, was largely influenced by the ecopolitical climate around him when he wrote about the concept of the growth pole. At this time, France was in its post-World War II phase of rebuilding itself under the Marshall Plan. Urban areas were the primary centers of economic growth, relying on technology- and innovation-based

industries that thrived on primary resources such as iron ore or agricultural products from the surrounding region. These concentrations of industries often affected the economies of geographical areas outside their immediate regions. Also apparent to Perroux was the dominance of colonial centers over geographically dispersed colonized areas.

Perroux's observation and belief was that concentrations of economic forces would develop in areas that could provide the material and infrastructural resources necessary for the establishment, sustenance, and growth of key industries. These resources contributed toward the economic growth of this cluster of industries and caused them to become key or "propulsive" industries that caused an economic thrust in related industries and businesses through "fields of (economic) forces." The thrust was not necessarily felt in the growth pole's surrounding region, or even within its country of location. Therefore, this concept recognized the forces of polarization but did not recognize geographic or political boundaries.

However, Jacques Boudeville and other interpreters of Perroux's growth pole concept replaced "economic space" with geographic space, an idea that was readily adopted by regional planners and economic geographers who were pressed into making economic development plans on a regional scale. The idea was to identify selected nuclei for industrial growth to stimulate development in the surrounding area instead of focusing on the underdeveloped region as a whole. This idea was then touted as a remedy for jump-starting the slumping economies of entire regions or inducing development into economically retarded areas.

As history has shown, this theory did not readily translate into practice when it was applied in the developing world, and growth could not be injected into a geographic region by adding a growth pole into it. A more comprehensive territorial approach seemed to be more appropriate for both rural and urban development. Even in the developed world, Dutch national planning experience aimed at correcting regional imbalances by earmarking less developed areas for growth during the 1950s and 1960s did not have the desired "spread effect" in the surrounding area. It has since been realized that the failure was not of Perroux's growth pole theory but of its faulty application as a space-bound concept, and a remedy for all regional underdevelopment.

Today, as economic interaction encompasses macroregions and becomes globalized, Perroux's original theory seems likely to find validation. A recent ex-

ample of such growth pole effects may be found in the Silicon Valley in San Jose, CALIFORNIA. The information technology (IT) industry here grew at a meteoric rate in the 1990s, but the economic stimulus was not restricted to the state of California or even the United States. Its impact was felt through increased employment and social development in the developing countries of Asia halfway around the globe.

## Guadeloupe

GADELOUPE, IN THE CARIBBEAN SEA, is one of the four French overseas departments (similar to states in the UNITED STATES). Guadeloupe is also a French region. There are two main islands, Basse Terre and Grande Terre, separated by a strip of water called the Rivière Salée. Other outlying inhabited islands are dependencies, namely Saint Martin, St Barthélemy, Désirade, Marie Galante, the Petite Terre and Saintes Islands. These territories are collectively known as Guadeloupe.

The climate is tropical and humid and the dry season runs from December to May (*carême*). During the rainy season (*hivernage*), June to November, temperatures generally rise. Guadeloupe's climate is tempered by trade winds, but hurricanes and cyclones often wreak havoc in the area. Neighboring islands in the southwest Caribbean include the UNITED KINGDOM'S ANGUILLA and the NETHERLANDS ANTILLES.

The landscape is mountainous in the west (Basse Terre), and thick forest covers the slopes and thins out nearer to the coast. The highest point in Guadeloupe is La Soufrière in Basse Terre, a live volcano. Low limestone plateaus and coastal cliffs are typical of Grande Terre in the East. The other outlying islands are mainly

volcanic. Approximately a third of the population lives in densely populated Point à Pitre on Grande Terre island.

Guadeloupe was colonized in 1635, and in spite of spells of British occupation in 1759, 1794 and 1810, the island remained a French possession. The native Indian inhabitants were massacred, and the bulk of today's black and mulatto population is descended from the slaves imported into Guadeloupe to labor on the sugar plantations. East Indians and some Chinese and Lebanese also contribute to the diversity of the population. Slavery was abolished in 1848, and the colony became an overseas department in 1946 and a region in 1982. As such, Guadeloupe is a member of the EUROPEAN UNION. The official language is French, but French Creole is spoken by the black and *métis* population.

Guadeloupe enjoys the same advantages as any other mainland French department or region in terms of health, education, and social welfare. The islands also benefit from special measures aimed at encouraging economic development (lower income tax for example). The islands are also popular tourist destinations for the French. Nevertheless, government subsidies are essential to Guadeloupe's economic survival.

UNIVERSITÉ PASCAL, FRANCE

## Guam

A U.S. TERRITORY, the island of Guam is one of the largest islands in the north PACIFIC OCEAN, located about three-quarters of the distance from HAWAII to the PHILIPPINES.

Its harbor, one of the best in the world, underlies the importance the island has held for the last five centuries to foreign powers in the region, first SPAIN, and now the UNITED STATES. Guam is the southernmost island of the chain known as the Mariana Islands and has been a territory of the United States since 1898. Much of the local economy is dependent on the U.S. military presence and on heavy subsidies, so it is un-

likely there will be any moves toward independence in the coming years.

The island is 48 mi (77 km) long and roughly 4 to 9 mi (6 to 15 km) wide. Its closest neighbors are the Northern Mariana Islands, a U.S. commonwealth, and the newly independent Federated States of MICRONESIA to the south. Guam lies at the crossroads of TRADE ROUTES, 1,488 mi (2,400 km) east of Manila (Philippines), 1,612 mi (2,600 km) south of TOKYO (JAPAN), and 3,658 mi (5,900 km) west of Honolulu, Hawaii.

Guam was formed by successive undersea volcanoes, which are older and more worn by erosion in the north, and younger in the south. The more hilly south has more streams and is thus more conducive to agriculture. The north is a coralline limestone plateau, with steep cliffs along the coasts. As part of the Pacific ring of fire, Guam also suffers from earthquakes. Coral reefs surround the island on all sides, causing some dangers for boats, which are increased by heavy swells and swift currents. Apra Harbor, located about 5 mi (8 km) southwest of the capital, is one of the best natural harbors in the Pacific, providing ample shelter during typhoons, which hit the island at least two times each year. The worst of these to strike in recorded history was in 1982, causing a great deal of damage.

The climate is maritime tropical, with little temperature variation, but increased rain during the southwest monsoons, July to October. Lush vegetation covers the island, with vines and palm trees, and tropical produce like bananas, breadfruit and coconut. Of particular value is the ironwood tree, termite resistant and extremely hard, now protected by law. There is limited natural wildlife, mostly birds, bats, insects, and sea turtles. The reefs have abundant tropical fish, squid and sharks. The nearby Challenger Deep in the Mariana Trench, at 35,838 ft (10,924 m) below sea level, is the deepest point on the planet.

The islands were populated by migrants, probably from the Philippines or Malay, who set up a number of chiefdoms based on matrilineal clans. Ferdinand Magellan landed here in 1521 on his way around the world and named the islands (the whole chain) the Ilhas das Velhas ("islands of sails" after the triangular-shaped sails used by the natives, known as Chamorros).

They were also sometimes called, pejoratively, the Ilhas de Ladrones ("thieves"). Although renamed by Spanish authorities the Marianas, in honor of the Queen of Spain, Mariana of Austria, the natives continued to call their island Guahan, or Guam. The Spanish did not settle here, but used it as a stop-off point in

their annual trade convoys between MEXICO and the Philippines. Jesuit missionaries arrived in the later 17th century, and permanent settlements began. Struggles with colonial administrators and the introduction of European diseases quickly reduced the native population from an estimated 50,000 to 100,000 in 1600 to a mere 5,000 by the end of the century, reaching record lows of about 1,500 in 1780. The United States took over the island from SPAIN in 1898 and established a large military presence; the island was at first essential as a coaling station for ships crossing the Pacific, then as a fueling stop for transpacific flights. After a brutal occupation by Japanese forces from 1941 to 1944, Apra Harbor served as a main airbase during the Vietnam War era.

Guam remains an unincorporated territory under the administration of the Department of the Interior. In a 1982 referendum, Guamanians requested commonwealth status, and a Guam Commonwealth Act, approved in two plebiscites, has been repeatedly submitted to Congress since 1988 but has been stalled, perhaps from U.S. military concerns on the island. Its culture is very American, and almost entirely urban. Most Chamorros seem happy with that, except there is a growing fear of being overwhelmed numerically by Filipino immigrants.

SMITHSONIAN INSTITUTION

## Guatemala

**Map Page** 1136 **Area** 67,661 square mi (108,890 square km) **Population** 13,909,384 **Capital** Guatemala City **Highest Point** 13,815 ft (4,211 m) **Lowest Point** 0 m **GDP per capita** \$3,900 **Primary Natural Resources** petroleum, nickel, rare woods.

THE REPUBLIC OF GUATEMALA is located in Central America and is bordered by the PACIFIC OCEAN, the Gulf of Honduras, otherwise known as the CARIBBEAN SEA, and four countries (EL SALVADOR, HONDURAS, BELIZE, MEXICO). The total length of the borders is about 1,296 mi (2,087 km), and the landscape is largely mountainous, with a limestone plateau. The two coastal areas are very narrow. Latino and Amerindian are the two major ethnic groups in Guatemala.

### VOLCANIC REGION

The mountainous areas of Guatemala are home to over 30 volcanoes. Many volcanoes are still active and this area experiences occasional earthquakes and volcanic eruptions. The Caribbean coastline is very narrow and beaches are nonexistent, while the Pacific coastline is characterized by black-sand beaches. Guatemala is intensely cultivated and agriculture employs 50 percent of the workforce; some people work on sugarcane and banana plantations.

Guatemala also features the Peten RAINFOREST, which is an archaeological treasure where many dinosaur bones can be found in the soil. However, the existence of the Peten rainforest, located within the interior of Guatemala, is being threatened as trees are being cut down. Soil erosion and water pollution also pose a great concern for the environment.

Guatemala has a tropical climate that varies with elevation. The country's coastal regions are generally hot throughout the year, with usual temperatures reaching up to 100 degrees F (38 degrees C). The summer seasons are hot and humid, while winters are warm and dry. These regions are susceptible to hurricanes and other tropical storms. The highlands are generally wet and cloudy during the summer, and the temperatures are not as hot as in the coastal regions because of the higher elevation. The climate in the Petén rainforest is mostly wet year-round. Summers are hot while winters are warm. There is a brief dry season from February to April. The rainforest is home to a variety of wildlife, which is in danger because of deforestation. The quetzal, the national bird, is almost extinct. Pumas, jaguars, ocelots, deer, tapir, and margay are among many of the animals living there.

## guerrilla base

A GUERRILLA BASE or base area is a physically secure geographic location used by political dissidents from which they can launch military attacks. Historically, such bases were local or national. In 2003, the process became global, with guerrilla bases of al-Qaeda staged in AFGHANISTAN, PAKISTAN, the PHILIPPINES, SUDAN, and possibly South America. Since guerrilla bases are not randomly located and must provide both security as well as political access, their locations become somewhat predictable.

Using special geographic areas for political dissidents is not new. However, in the 1920s, Mao Zedong in CHINA developed specific guidelines for the location and geopolitical nature of such bases. For optimum political impact as well as general security of the participants, such bases should meet as many of the following location or geographic criteria as possible:

1. It is best if an area or group has had previous experience in anti-government protests or activities.
2. Ideally, a base should be located where there are multiple political or administrative boundaries that create confusion in terms of local government authority.
3. A location should be chosen that provides access to a multiplicity of political targets that are demographic, economic, or political.
4. The area selected should provide some kind of physical advantage against government military attack, for example, mountains, jungles, swamps, distance from formal military units.
5. To the extent possible, the location should be capable of economic self-sufficiency. That is, it should be largely invulnerable to the withholding of food or essential supplies.

The use of these geographic conditions can be applied at all scales, from national to regional and even in an urban context with appropriate modifications, for example, high-rises and slums may equal rugged topography and jungle analogues. The key is target access and personal safety. It is the objective of these groups that distinguishes them from simple bandit hideouts like those used by Jesse James and others.

The ultimate objective is for each base area to become a proto-province or political unit. The creation of many base areas begins to form a geopolitical system and eventually an entire insurgent state. This was a calculated process in China during the civil war and has

been used with varying degrees of success in almost all modern guerrilla wars.

The modern variation on this process is where an insurgent political movement (in this case, al-Qaeda) seeks to create bases among sympathetic concentrations of Muslims, regardless of where they may be located (Detroit, MICHIGAN, or the southern Philippines). The process is the same. Find a sympathetic population and locate in an area that has access to political targets yet provides some physical safety. In some instances, this safety has been provided by a sympathetic national government as in Afghanistan under the Taliban, and in Pakistan or YEMEN at various times.

## Guinea

**Map Page** 1113 **Area** 94,925 square mi (245,857 square km) **Population** 9,030,220 **Capital** Conakry **Highest Point** 5,748 ft (1,752 m) **Lowest Point** 0 m **GDP per capita** \$340 **Primary Natural Resources** bauxite, iron ore, diamonds, precious metals.

GUINEA IS LOCATED in the southwestern part of West Africa. It is bordered by GUINEA-BISSAU, SENEGAL, and MALI to the north, by CÔTE D'IVOIRE to the east and southeast, by LIBERIA and SIERRA LEONE to the south, and by the ATLANTIC OCEAN to the west. Guinea is a humid tropical country with four main geographic regions.

There are alluvial coastal plains in Lower Guinea; the mountainous Fouta Djallon highlands in Middle Guinea, with an average elevation of 3,000 ft (915 m); the northern savanna in Upper Guinea; and the south-

eastern rainforest in Forest Guinea, which includes the Nimba Mountains.

Lower Guinea, also known as Maritime Guinea, stretches from the Atlantic Ocean inland to and including the foothills of the Fouta Djallon mountains. Tides along the coast are very high, reaching 15 ft (4.5 m), and creating an area of brackish marshes and estuaries that stretch many miles inland. Past these swamps is the alluvial plain, which is on average 30 mi (48 km) wide. Periods of heavy rain cover these plains resulting in soggy soil, but this along with the equatorial heat favor agriculture in this area. The people of Guinea grow rice, millet, maize, oil palms, kola trees, and in the southern part of Lower Guinea, bananas and pineapples. Originally living in this area were the medieval Ghana people; later it became part of the Mali Empire. Currently, the Soussous inhabit this area.

Middle Guinea is covered by the Fouta Djallon Mountains, which consist of a mass of complex, elevated, relatively level plateaus. In many places, these plateaus are cut with deep, steep-walled valleys. Most of these valleys extend for long distances; many are at right angles to each other, creating a checkerboard appearance to the region. Many of the major African rivers begin in this area, including the Gambia, the Senegal, the NIGER, and 19 others. Living in Middle Guinea are the Peuhl, who raise cattle in the highlands.

Upper Guinea stretches east of the Fouta Djallon and is covered in tall grass savannas. This area is cut by a long rocky spur stretching eastward along the Mali border for over 100 mi (160 km). Some shorter spurs also stretch east from the Fouta Djallon. Along the western border with Mali are rounded granite domes rising above the plains. This area is inhabited by the Malinke people, who also make up part of the inhabitants of the Forest region.

Forest Guinea covers the southeastern corner of Guinea. This area has several peaks above 4,000 ft (1,220 m). Many of these peaks are lightly forested and have crests of bare rocks. Below 2,000 ft (610 m), this area is covered in dense rainforest. The Malinke and other small groups, including the Gerze and Toma peoples, inhabit this area. They raise cattle and cultivate crops of rice, maize, cassava, bananas, coffee, kola trees, and oil palms.

FRANCE gained control of Guinea in 1898 when it defeated the armies of Samori Touré, a warlord and leader of Malinke descent. The French negotiated for the boundaries of Guinea that are in use today. On October 2, 1958, France withdrew from Guinea in the face of the Democratic Party of Guinea, led by Sékou

Touré and backed by almost the entire native population of Guinea. Guinea became a dictatorship until Touré's death in 1984. Since then, President General Lansana Conté has created civilian rule and democratic reform in Guinea.

## Guinea-Bissau

**Map Page** 1113 **Area** 13,942 square mi (36,120 square km) **Capital** Bissau **Population** 1,360,827 **Highest Point** 984 ft (300 m) **Lowest Point** 0 m **GDP per capita** \$700 **Primary Natural Resources** fish, timber, phosphates, bauxite, petroleum.

THE REPUBLIC OF Guinea-Bissau, commonly called Guinea-Bissau, is a tropical West African nation-state. The borders include the ATLANTIC OCEAN on its west, GUINEA to its south and east, and SENEGAL to the north. Guinea-Bissau is an ethnically diverse country. While most of its residents are indigenous Africans, they belong to various ethnic groups. Thirty percent belong to the Balanta group, 20 percent are Fula, 14 percent are Manjaca, 13 percent are Mandinga, and 7 percent are Papel. The remaining are of European descent or mixed African and European ancestry.

Approximately 50 percent of the population adheres to indigenous African religions that recognize many deities and venerate ancestors. Forty-five percent identify themselves as Muslims and 5 percent as Christians. Portuguese is the official language of the country, although such native languages as Fulah and Mande are also in wide use.

The area was home to agricultural groups during the European Middle Ages. In the centuries before European contact, Guinea-Bissau underwent profound cultural, political, and population shifts. During the

early 13th century, the displaced Soninke, an ethnic group from GHANA, fled to Guinea-Bissau when the Almoravids subjugated Ghana. Later, the area became a coastal outpost of the Mali Empire.

Portuguese advancement in ocean navigation and their desire for new sources of wealth combined in the mid 1400s to lead Portuguese explorers to northern and western Africa. Portuguese slave traders captured Guineans and sent them to plantations on CAPE VERDE, an island group off Guinea-Bissau's coast. In the late 1600s, Guinea-Bissau became PORTUGAL's first colony on the African continent. Despite pressures from other European colonial powers and colonized ethnic groups, Guinea-Bissau remained under Portuguese authority until 1974, when, after a 10-year war of independence led by the African Party for the Independence of Guinea and Cape Verde, the Republic of Guinea-Bissau was proclaimed.

The first 30 years of independence were fraught with difficulty. In 1980, Guinea-Bissau's first president, Luis de Almeda Cabral, was overthrown by Prime Minister João Bernard Vieira. Supported by the military, Vieira ruled for 18 years, during which several unsuccessful coups were staged, political opposition was crushed, and ethnic tensions increased. Since 1998, Vieira and Kumba Yala, elected in 1998, have been deposed from power by coups.

Partly because of political turmoil, an undeveloped infrastructure, and a dependence on subsistence agriculture, Guinea-Bissau languishes in poverty. Today, the country is one of the poorest nations in the world. Using key health indicators for 2001, poverty has compromised Guinean health. At birth, for example, Guinean women have only a 40.6-year life expectancy. Men are expected to live 36.1 years. Infant mortality rates of 195 and 213 per 1,000 live births for Guinean female and male children, respectively, rank among the highest in African regions according to the World Health Organization. Economic and health improvements are possible with international effort but only through sustainable growth projects that take the natural environment, citizens, and industry into consideration.

As a republic, Guinea-Bissau is in its infancy, and as the 21st century unfolds, whether it matures into a stable country will be determined by its people and their leaders.

## Gulf of Aqaba

THE GULF OF AQABA is the north arm of the RED SEA; it is bordered by ISRAEL, JORDAN, EGYPT, and SAUDI ARABIA. Created by seismic activity along the Afro-Syrian Rift, it is the northernmost extension of the Red Sea. It is a semi-enclosed water body that extends south some 111 mi (180 km) from Eilat and Aqaba and joins the Red Sea at the Straits of Tiran, with its widest point spanning 17 mi (28 km).

Israel's gulf shore extends only a few kilometers, from the city of Eilat to the border with Egypt at Taba. Jordan's shore reaches some 12 mi (20 km) in length, before meeting with the Saudi Arabia border. Egypt enjoys the longest gulf border, which stretches some 105 mi (170 km) along the SINAI PENINSULA between Taba and the Straits of Tiran. The Gulf of Aqaba supports a world class coral reef ECOSYSTEM that is noted for its intense beauty and accessibility. The gulf is exceptionally deep, as much as 5,905 ft (1,800 m) in some points, with an average depth of 2,624 ft (800 m). Because of its desert environs, very little freshwater flows into the Gulf of Aqaba and its southern mouth at the Strait of Tiran is extremely narrow. As a result of these factors, the gulf is a highly saline, still environment, with limited hydrological interface with the Red Sea.

Waters that have been used for centuries for fishing, trading, and the transport of religious pilgrims are today shared with oil tankers, massive cargo ships, and growing fleets of tourists. These increased high-impact and potentially devastating uses are of concern. Increased international and regional cooperation regarding conservation, pollution, and sustainable use have been encouraging.

In May 1967, during a time of attempted pan-Arab nationalism, President Abdul Nasser of Egypt closed the Gulf of Aqaba by blockading the Straits of Tiran and pledged that "under no circumstances will we allow the Israeli flag to pass through the Aqaba Gulf." Israel's military reaction gave proof to the Gulf of Aqaba's strategic and political importance to the na-

tions of the region. The Straits of Tiran played a critical role in the Arab-Israeli 1967 war, was returned to Egypt in the wake of the 1973 war, and has been monitored by a multinational peacekeeping force since 1982.

Lying along the international waterway through the Suez Canal, the Gulf of Aqaba is a natural transshipment area. Improved relations among the bordering nations have encouraged the development of the Aqaba-Eilat region as a commercial gateway between Asia, Europe, and Africa. Continuing improvements of the ports and transportation infrastructure have increased the Gulf of Aqaba's role as a regional transshipment point between the MAGHREB countries and the PERSIAN GULF. Future proposals include upgrading the Port of Aqaba, establishing inland logistic centers, improving transportation networks, building manufacturing and storage facilities, and creating international passenger and commercial airports. This complex would then be connected to other Red Sea and MEDITERRANEAN SEA ports by railroad. Such ambitious projects and proposals have been presented by the Jordanian, Israeli and Egyptian governments.

## Gulf Stream

THE GULF STREAM, a relative newcomer on the geological scene, is an odd, fast-moving circulation of warm water that travels in an unfixed position, a few hundred miles north of FLORIDA, up the east coast of the UNITED STATES to Cape Hatteras, NORTH CAROLINA, then onto Nantucket Island, before kicking eastward across the ATLANTIC OCEAN to the British Isles.

In this way, the Gulf Stream, a part of the western edge of the North Atlantic circulation, acts as a boundary that prevents the warm water of the SARGASSO SEA from overflowing the colder, denser waters on the inshore side.

The Gulf Stream is one of the strongest and most extensive known currents in the world, and it is separated from the United States by a narrow strip of cold water. The Gulf Stream, which can be as much as 50 mi (80 km) wide and 1,300 ft (400 mi) deep, is caused by the northeast and southeast trade winds on the surface of the water and the equatorial currents that meet in the region of the windward islands of the CARIBBEAN SEA.

The Gulf Stream's rival, the KUROSHIO CURRENT, located along the western edge of the PACIFIC OCEAN and the coast of JAPAN, is part of a transpacific system that connects the North Pacific, California, and equatorial currents. The Gulf Stream triples in volume and is strengthened by the waters from the Florida Straits, by way of the Florida Current, and by currents coming from the northern and eastern coast of PUERTO RICO and the BAHAMAS. It can travel more than 60 mi (96 km) a day.

The Gulf Stream, first mapped by Benjamin Franklin and his American whaling captain cousin Timothy Folger, early pioneers in using temperature in an attempt to define its boundaries, maintains its dimensions for nearly 1,000 mi (1,610 km) up the East Coast of the United States. Franklin, using observations of current speed in the region of the Gulf Stream and plotting them on a chart, was able to draw a river traversing the Atlantic Ocean with speeds ranging from 4 to 2 knots.

The strong carry power of the Gulf Stream's warm equatorial layers of water has a notable, almost direct effect on the climate in various parts of the Earth. As the Gulf Stream moves past Cape Hatteras, NORTH CAROLINA, it begins to flow away from the East Coast of the United States. The altered flow of the Gulf Stream, known as meanders or eddies, separates the cold slope water to the north from warm Sargasso Sea water to the south. As the Gulf Stream flows into deeper water, it carries warm water to the North Atlantic region, as it enters the Norwegian Sea between the FAROE ISLANDS and Great Britain. Thus, the Gulf Stream, which bathes northwest Europe with warmer water and wind currents, is largely believed to be the reason for mild European climate.

Too warm to encourage the kind of fish that are the main catch of North Atlantic waters, the Gulf Stream does bring well-developed specimens of tropical fish, like the Portuguese man-of-war jellyfish, much farther to north than they would normally venture. In addition, there are two particular species of plant (the double coconut tree indigenous to JAMAICA) and animal life

*The Gulf Stream has attracted the attention of many scientists and is probably the most studied example of ocean circulation.*

(the freshwater eels of Europe) that are carried for thousands of miles by the Gulf Stream surface transport system to the shores of IRELAND and Scotland.

Because the current patterns of the oceans has been the same as it is today throughout historical time, it becomes easy to understand that the Gulf Stream played an important role in the history of the New World. Indeed, it was during the early days of discovery of the West Indies, including the large islands of CUBA, HAITI, and Jamaica, that the Gulf Stream was first reported by Juan Ponce de Leon. During the American colonial period, the principal ocean routes for New England traders of rum and sugar and species—the direct northerly route influenced by clockwise circulation of the North Atlantic and the southwest route influenced by the clockwise currents northward past Florida—played their part in the development of North America. Through the advent of frequent voyaging between the Old World and the New, the Gulf Stream came into its own as the most comfortable homeward route from the West Indies to Europe.

As we now understand, the Gulf Stream can be regarded as merely the outer edge of a general rotation of the surface waters of the North Atlantic. As such, it deserves its popularity with mankind because, in general, it has a benign influence on man's affairs. The Gulf Stream has attracted the attention of many investigators and is probably the most studied example of ocean circulation. Although it can be questioned whether the

Gulf Stream should be considered as a separate entity or regarded as the outer edge of the North Atlantic circulation, it is still one of the largest and fastest of the water circulation of the seas. It has always played an important role in the lives of people who live on the land that borders the North Atlantic.

UNIVERSITY OF NORTH CAROLINA, WILMINGTON

## Guyana

**Map Page** 1140 **Area** 76,772 square mi (196,850 square km) **Population** 702,100 **Capital** Georgetown **Highest Point** 9,355 ft (2,835 m) **Lowest Point** 0 m **GDP per capita** \$4,000 **Primary Natural Resources** bauxite, gold, diamonds, hardwood.

**THE NAME** *Guyana* possibly comes from a local native word meaning “land of water,” but it could also derive from the word for “honorable people.” These Carib roots help demonstrate Guyana’s difference from the rest of the South American continent as one of the three non-Hispanic states on the northeast coast, wedged between VENEZUELA, BRAZIL, and SURINAME. Culturally, linguistically and economically, the three Guianas (along with Suriname, formerly Dutch Guiana, and FRENCH GUIANA) belong to the Caribbean region, and have been members of Caribbean regional associations since their inception.

The former British Guiana has a coastline of 285 mi (459 km), with the rest of the country stretching inland, encompassing the watershed of the largest river, the Essequibo, as it drains from the Guiana Highlands to the ATLANTIC OCEAN. The coastal regions are swampy, with river estuaries that provide an abundant harvest of shrimp, one of Guyana’s major exports. Much of this area is below sea level and relies on exten-

sive dykes and drainage systems; still many houses are built on wooden stilts. The interior gradually increases to small hills, forest uplands, then mountains (the Pakaraima Mountains, up to 3,000 ft or 915 m shared with Venezuela and Brazil). Unlike the other two Guianas, Guyana also extends south of this band of mountains, into an area of tropical savanna grassland. Aside from this, forests cover approximately 80 percent of the country.

Hardwoods are exported and used for the manufacture of wood products, but forestry is possible only in areas accessible by existent roads or navigable rivers—both very limited beyond the first foothills. The frontier between lowlands and highlands is marked by striking natural features, including Kaieteur Falls, one of the highest waterfalls in the world (total drop of 822 ft or 250 m).

The highlands also contain significant mineral wealth, especially gold, but also diamonds, manganese, copper, and molybdenum. Bauxite (used to produce aluminum) was a big business in Guyana since the opening of the Demerara Bauxite Mining Company (DEMBA) in 1917. Reynolds Metal Company followed in 1953, and these two companies formed an essential component of the country’s economy.

After independence from Britain in 1966, both companies were nationalized, and production declined in the following decades, until production was stopped altogether in 1983. Other resources remain unexplored and are potentially significant (iron, lead, silver, platinum) but are located too far from main roads or rivers to be commercially viable, and claims from Venezuela to nearly 70 percent of Guyana’s territory (the land west of the Essequibo) have also deterred some foreign investors.

The remoteness of much of southern Guyana was also an attraction for the People’s Temple cult, originally from the UNITED STATES, which made international headlines in 1978 after the mass suicide/murder of nearly 1,000 of its members.

## Hainan Island

THE SECOND-largest island (after TAIWAN) in CHINA with an area of 13,104 square mi (33,940 square km), Hainan Island is the most southerly province located in the South China Sea. The island is situated south of Guangdong province and west of VIETNAM. The topographic structure of the island resembles a staircase, with towering mountains in the middle and descending hills, plateaus, and plains toward the periphery.

Hainan Island enjoys a tropical maritime climate with abundant rainfall and year-round sunshine. The annual average temperature is about 77 degrees F (25 degrees C) and the average rainfall is 63 in (160 cm). Winter and spring are considered the dry seasons, while summer and autumn are wet. Good sunlight, heat and water allow a rich variety of crops like rice, tropical fruits, and coconut to be cultivated on the island. It is rich in mineral resources such as salt, natural gas, iron ore, and oil.

But the island is also exposed to tropical storms and typhoons that hit the southeastern coast from July to September. Although geologically stable, it has a history of volcanic eruptions and mild earthquakes. Diseases ranging from malaria to mosquito-borne viruses plague the island.

Hainan Island is home to over 4,200 plant species and some 560 animal species, making it a destination

for researchers. But deforestation could well threaten species extinction. The island is also a growing destination for tourists. Mainland Chinese and foreigners mostly flock to the southern coastal city of Sanya for surf and sun. In addition, the island has played host to international events like the Miss World Contest and Boao Forum for Asia.

Historically, the Li ethnic peoples were the first to inhabit the island 3,000 years ago. Other ethnic groups include the Miao and Hui peoples. The Han Chinese form the majority group. Backward and remote, the island was a place for exiles. In the early 20th century, many Hainanese emigrated abroad in search of a better life. Today, about 2 million Hainan Chinese are scattered in 53 countries worldwide.

In 1988, the island was made a special economic zone to boost foreign investment. The gross domestic product has increased tremendously, but economic development has gone through some boom-and-bust cycles. While rubber and agriculture are traditional industries, tourism, petrochemicals, biopharmaceuticals and machinery and electronic industries are expanding.

## Haiti

**Map Page** 1137 **Area** 27,750 square mi (44,658 square km) **Population** 7,527,817 **Capital** Port-au-Prince **Highest Point** 8,792 ft (2,680 m) **Lowest Point** 0 m **GDP per capita** \$1,400 **Primary Natural Resources** bauxite, copper, calcium carbonate, gold.

HAITI IS LOCATED on the western third of the island of Hispaniola in the CARIBBEAN SEA. The country is mainly mountainous, with 60 percent of the land on gradients of at least 20 percent. The mountain ranges of Massif de la Hotte, the Massif de la Selle, and the Chaîne du Bonnet encompass much of the land. Two large peninsulas are present in the country. The peninsulas are separated by the Golfe de la Gonave.

The fertile river valleys and deep forests, which once provided beautiful sights, have diminished to a few. Haiti has suffered from deforestation, which has left only three percent of the land untouched. Much of the nutrient-rich topsoil has been washed away into the surrounding waters, which has destroyed some of the marine life. Because of the distinct range of elevations, the country has numerous plant species: 5,000 are spread throughout the land, including 600 fern and 300 orchid species. These plants thrive in the hot and humid climate throughout the year, with temperatures ranging from 65 degrees F (20 degree C) to 85 degrees F (30 degrees C).

The history of Haiti is full of turbulence. After almost 200 years of rule, SPAIN ceded the western portion of Hispaniola to FRANCE in 1697. This area named Saint Dominique soon became one of the wealthiest nations in the Caribbean. Sugar plantations arose throughout the nation, and slaves were brought over in large numbers.

In 1791, a slave revolt, led by Toussaint Louverture, broke out across the colony. Louverture named himself lieutenant governor of the state in 1796. How-

ever, in October 1801, after a victorious campaign in Europe, Napoleon ordered an expeditionary force to Haiti to reclaim its lost colony. By November 1803, the last of Napoleon’s forces were routed and on January 1, 1804, the war-ravaged colony was soon declared independent of French rule and renamed Haiti.

In 1844, Santo Domingo (soon renamed the Dominican Republic) declared its independence from the struggling country. Haiti seemed to be spiraling into obscurity in the world stage. From 1843 to 1915, 22 dictators ruled the country. In 1915, the UNITED STATES invaded Haiti hoping to create stability in the country. By 1937, the American troops left the country, with the belief that the country was a modernized and thriving.

For the next century, the Haitian government continued to struggle. During World War II, increased world market prices increased Haitian trade and greater exports. However, after the fighting ended, the country was still mired in poverty. François Duvalier was elected president of the country in 1957. Throughout his power, Duvalier struggled with the Catholic Church and citizens fleeing the country. He died in 1971, but his son, Jean-Claude Duvalier, took over the position. The Haitian economy continued to suffer and its external public debt increased to a staggering \$366 million in 1980. The Haitian people continued to flee.

During January 1986, urban resistance overspread the country, led in particular by Jean-Bertrand Aristide. On February 7, 1986, Duvalier left Haiti, and General Henri Namphy, with American support, took control of the country. The Haitian government continued to promise the United States that elections would occur in November 1987. Three years later, Aristide won the presidential election. He took office in early 1991 but was overthrown by a violent coup.

During this three-year period, a military de facto regime ruled the country and refused to return to a constitutional government. The United Nations ultimately passed a resolution and sent in a multinational force to restore order in the country. Before the American-led force actually stepped into the country, a deal was brokered, which the Haitian de facto government peacefully accepted. Aristide was returned to the country, where he became president and the constitutional government was restored under the watchful eye of the United Nations.

For the next 10 years, the international optimism surrounding Aristide slowly diminished. He became embroiled in a variety of corruptive practices and many questioned the fairness of the presidential elections. Opposition parties rose and by early 2003, violence

from all political sides began to flare up once again. In February 2004, Aristide fled Haiti, and afterward, U.S. Marines arrived along with 3,600 other international peacekeepers, to stabilize the situation. Haiti once again is trying to reestablish itself from its troubled past.

## hammada

**HAMMADA** IS AN Arabic word used to describe "desert pavement." The deserts of the world that have sand dunes capture the imagination, but many of the world's desert areas are bleak, stony deserts. Usually, the stony deserts are level plains that are virtually devoid of vegetation and also have very little, if any, soil. These deserts can have a relatively smooth, rocky surface that is hard, like road paving. Hammadas form in regions where the soil is either saline or alkaline, with little ability to absorb water, and winds are strong.

Desert paving or hammada (North Africa) is called by a number of names in the different hot and cold deserts of the world. The names are banada, desert crust, deflation armor, desert armor (North America), desert pavement, GOBI (CHINA), gibber (AUSTRALIA), lag gravel or reg (Africa, if the fine material remains), serir (Africa, if no fine material remains) and stone pavement.

Hammada describes a dark, stony desert surface without sand or vegetation. The dark color is "desert varnish" caused by wind-borne clay particles that carry bacteria living on them. The particles coat the rocks of the pavement coloring them with a dark sheen.

Desert regions covered with hammada have a surface that is fairly smooth. The wind has blown away most of the sand, soil, and dust. A layer of rocks on bedrock has formed that is so tightly packed that it forms a solid surface. There may be a layer of soil or

dust under the hammada, but it can form directly on top of clean bedrock. The bare rocks that form hammada surfaces are usually relatively small and fit as tightly as a mosaic. Earth scientists describe these rock fragments as either primary or secondary. The primary stones are usually coarse, while the fine secondary material comes from the disintegration of the larger primary material.

There are several geomorphic theories explaining how hammada forms. One theory is that the pavement is a lag deposit. This theory says that the rock fragments of the pavement are what remains after the wind has blown away (deflated) all the small, fine-grained sand and dust. A second theory argues that moving water has deflated all of the fine material, leaving the hammada material behind to form the desert pavement.

A third theory sees the cycles of wetting and drying of the material as the cause. The exact nature of the process is not fully understood. Some claylike soils expand when wet, which forces stones to move upward. Another theory says that salt acts like water does when it expands or contracts in the freezing or melting process to create a stony surface. Another theory is that hammadas are caused by chilling and heating, as mechanisms that push stones to the surface of the desert and keep them there. Another theory is that several physical processes move the fine particles of sand and dust down between the stones of the hammada surface.

Hammada has been found on ALLUVIAL FANS, in dry WADIS, in terraces, on plateaus, on plains, and on bedrock. It is believed that hammada is also on the surface of the windswept planet Mars. Since hammada forms in such varied deserts conditions, it may be that all the theories are correct explanations.

The surfaces of many hammadas are hard enough for planes to use as landing strips. Vehicles can travel across the more solid variety, but excessive use can cause dust to rise from particles below the hammada surface. In the Atacama desert of Peru, the ancient Nazca people used hammada to make enormous drawings.

Tank battle maneuvers and tank battles in North Africa, KUWAIT, and IRAQ have disturbed large areas of hammada, causing dust and sand dunes to form elsewhere. The damage to these deserts will take many years for nature to repair.

## Hawaii

HAWAII IS a U.S. state located in the central PACIFIC OCEAN near the EQUATOR and consists of eight major islands: Hawaii, Maui, Kahoolawe, Lanai, Molokai, Oahu, Kauai, and Niihau; 129 smaller islands are also

The high cliffs and rough coasts of Hawaii are a result of the volcanic origin of the Pacific Ocean islands.

part of Hawaii. Hawaii is not the equivalent of the Hawaiian Islands or the Hawaiian Chain, which includes other islands, such as Midway, that are not part of the state of Hawaii. At its greatest expanse, Hawaii extends for 1,523 mi (2,600 km); it has a total land mass of 6,423 square mi (16,729 square km). The highest point is Mauna Kea at more than 13,796 feet (4,205 m) and the lowest point is at sea level. The capital city is Honolulu on the island of Oahu. The population of Hawaii is 1,211,537 (2000 census), and its largest city is Honolulu (876,156). The state population is evenly divided by gender and has a density of 188.6 persons per square mile. The median age in 2000 was 36.2 years.

The island of Hawaii is the largest of the islands and has two active volcanoes, Mauna Loa and Kilauea; it supports extensive agricultural activity. Maui is called the Valley Island because of the dominance of two volcanic mountains; while a haven for tourists, Maui also has sustained valuable production of sugar. Kahoolawe is a small, uninhabited island near Maui. Lanai is the center of the pineapple business. Molokai, also near Maui, is an island of canyons and mountains; its central region is fertile for crops. Oahu has two mountain ranges, the Koolau Range in the east and the Waianae Range in the west. While supporting an expanding metropolitan Honolulu, Oahu is an agricultural center with sugar and pineapple plantations. Kauai, known as the Garden Island, is rugged; its Mount Waialeale has the greatest rainfall (460 in or 1,168 cm) per year on Earth. Niihau is rather arid; it is privately owned by the Robinson family of Kauai.

Hawaii's gross state product in 2000 was \$39.1 billion. The economy is based on tourism (\$10.9 billion), U.S. military defense spending (\$4.4 billion), and the sugar and pineapple businesses (\$276.1 million.) The Hawaiian state government is interested in diversifying the economy and has invested in developing science and technology, film and television production, sports, oceanic research and development, education, and floral and specialty food products. In trade, Hawaii transacted \$3.31 billion in merchandise in 2000 and had exports totaling \$407.7 million. Imported petroleum products provide more than 90 percent of Hawaii's energy requirements (2000).

Originally settled by Polynesians more than 1,500 years ago, Captain James Cook was the first European to visit Hawaii (1778). During the 19th century the native Hawaiian population (estimated about 300,000) was decimated by diseases imported by European and American adventurers, businessmen, and missionaries.

By 1900, the native population had been reduced to about 70,000. During the same time, American immigrants overthrew the native government and moved Hawaii to annexation by the UNITED STATES. American expansion in Hawaii and the PHILIPPINES was denounced as imperialism; for the most part, American culture absorbed Hawaiian culture, although recent years have witnessed a resurgent native Hawaii culture. Americans viewed Hawaii as strategically and economically significant; the American navy centered its Pacific headquarters in Hawaii, and American businesses reaped profits from sugar, pineapple, and other fruit products. The attack on Pearl Harbor and the subsequent war against Japan led to an expanded American presence in the Pacific.

During the second half of the 20th century, the United States relinquished its naval bases in the Philippines and became dependent upon Hawaii as the focal point for its Pacific fleet. Further, the naval observatories on Hawaii are important astronomical centers for research and satellite management.

## Heard and McDonald Islands

TWO OF THE MOST isolated spots on the globe, the Heard and McDonald Islands have only been visited a few times, and much remains to be discovered about them. The islands are located at the bottom of the world, where the INDIAN OCEAN meets the Antarctic seas, and have recently been declared a United Nations UNESCO World Heritage site due to their pristine natural habitat, nearly untouched by human hands.

The first sighting of the larger island, Heard, is attributed to the British captain Peter Kemp in 1833, but also to the American captain John J. Heard, in 1853. Much smaller McDonald island, 27 mi (43.5 km) to the west, was spotted a year later by British captain William McDonald. Hunters, in the 1850s to 1870s,

nearly depleted the islands of their population of varieties of seals (notably elephant seal and fur seal), king penguins and whales, but these populations have now mostly returned to their former numbers. To further protect this wildlife, the government of AUSTRALIA established the Heard Island and McDonald Islands Marine Reserve in 2002. Thirty-four species of bird come here to breed, including penguins, albatrosses, and giant petrels. Human visitors are tightly restricted to occasional scientific expeditions.

The islands, about 1,000 mi (1,700 km) off the coast of ANTARCTICA, are the most volcanically active in the sub-Antarctic region. They are rises on the Kerguelen Plateau, which also includes the Îles Kerguelens, about 434 mi (700 km) to the northwest (territory of FRANCE). Neither of the islands has much vegetation, though kelp is abundant offshore. Rain or snow and extensive cloud cover keep the islands very wet most of the year and are accompanied by nearly constant high winds. Heard Island is a circular volcanic cone, dominated by the Big Ben Massif topped by Mawson Peak, the only active volcano in Australian territory. A mountainous headland extends 6.2 mi (10 km) to the northwest (Laurens Peninsula), connected by a narrow ridge little more than 330 ft (100 m) wide. Heard is surrounded by numerous outlying rocks, islets and reefs. A few kilometers offshore are the Shag Islands.

About 80 percent of Heard is glaciated, with ice up to 495 ft (150 m) deep. Ice cliffs make up much of the coast, adding to the island's inaccessibility. The McDonald Island group is made up of one volcanic peak and several smaller rocky islets (Flat Island, Meyer Rock).

Much smaller than Heard, McDonald has been landed on only twice in its history, and very little is known about it. In fact, the size of McDonald seems to have recently doubled—from .39 square mi (1 square km) to an estimated 1 square mi (2.45 square km)—through a volcanic eruption sometime between 1997 and 2001, when changes were detected on a satellite photograph. It is believed that this eruption is continuing, radically altering the shape of McDonald Island.

## heartland

THE HEARTLAND THEORY was developed by Scottish geographer, Sir Halford J. MACKINDER. He read his paper "The Geographical Pivot of History" before the Royal Geographical Society in London in 1904, and soon afterward published his views on the influence of geography on politics in the *Geographical Journal*.

Mackinder's argument introduced into POLITICAL GEOGRAPHY the view that the globe could develop into two power blocs. The center of world power lay in the "heartland." This was roughly the territory east of the DANUBE RIVER to the URAL MOUNTAINS. Mackinder claimed that whoever unified and dominated Central and Eastern Europe would be able to control the three continents of the "World Island"—Europe, Asia, and Africa. His hypothesis, which became famous, was: "Who rules Eastern Europe commands the Heartland. Who rules the Heartland commands the World Island. Who rules the World Island commands the world." The other power bloc, because of what he viewed as the relative decline of sea power, was the "maritime lands."

Mackinder had rejected the theory of sea power as the key to world domination proposed in *The Influence of Sea Power upon History* by Captain Alfred T. Mahan of the U.S. Navy. Mahan developed a number of factors of state power, such as geographical position, extent of territory, population, and national and governmental character to explain state power. Mahan had used his study to propose policies for the American government to follow. These included annexing the Hawaiian Islands, controlling the CARIBBEAN SEA, and building a canal across PANAMA. Theodore Roosevelt was to use these ideas as the basis of his foreign policy.

In contrast, Mackinder claimed that land-based power was increasing in scope because of improvements in communications, transportation, and armaments. The heartland power would be the ultimate land power that would be impossible to expel from its natural fortress. He believed that there was a Eurasian core that would be impregnable to naval power. As the center of a great fertile landmass, it would be difficult to penetrate with sea power and easily defended with land forces.

Mackinder's views were read and discussed by many people immediately. His hypothesis soon became one of the most intensely debated ideas in the history of geography. Mackinder's views were eagerly accepted by a number of German politicians. In particular by Karl Haushofer, who with others adopted a *geopolitik*

program. Their views influenced Adolf Hitler, who used them as a rationale for conquering Europe.

Among those who disagreed with Mackinder's theory was N.J. Spykman. He argued that Mackinder had exaggerated the Heartland's potential for power. The real power was not in the "pivot," as Mackinder had termed the heartland, but in what Mackinder had called the "inner crescent" or the "rimland" in Spykman's terminology. Spykman's hypothesis became, "He who controls the Rimland rules Eurasia; Who rules Eurasia controls the destinies of the world."

Missing from the heartland theories of Mackinder and Spykman was air power. In 1943 Mackinder dismissed air power as a technological change that would make a difference in the balance of power. However, in 1950 A.P. de Seversky argued that the key to American survival and supremacy was air power.

Another critic of Mackinder was A.R. Hall. In 1955, Hall argued that Mackinder had ignored the existence of another "heartland," namely the Anglo-American alliance.

In 1956, D.W. Meinig proposed changes to Mackinder's heartland theory and to the rimland theory. His criticism included changes to the definitions and criteria of Mackinder's theory. In 1964, D.J.M. Hooson extended the heartland theory by identifying the "core" areas, such as the industrial centers.

In the last quarter of the 20th century, two major groups debated and extended Mackinder's ideas. The first group was composed of specialists in strategic studies. One important representative of this approach was Colin S. Grey, who published *The Geopolitics of the Nuclear Era* (1979). The other group was composed of scholars in traditional POLITICAL GEOGRAPHY. These included authors such as Geoffrey Parker (*Western Geopolitical Thought in the Twentieth Century* 1985), among others.

After World War II, the Soviet Union effectively controlled the heartland. Mackinder, however, had proposed ideas of an Atlantic community in 1924 that developed into the NORTH ATLANTIC TREATY ORGANIZATION (NATO). In addition the Cold War policy of containment of communism was, in effect, a siege of "fortress" heartland. Global politics of the 20th century were deeply influenced by Mackinder's geopolitical vision. The War on Terror is also being waged with a geopolitical eye on the Middle Eastern "rimland."

## hemisphere

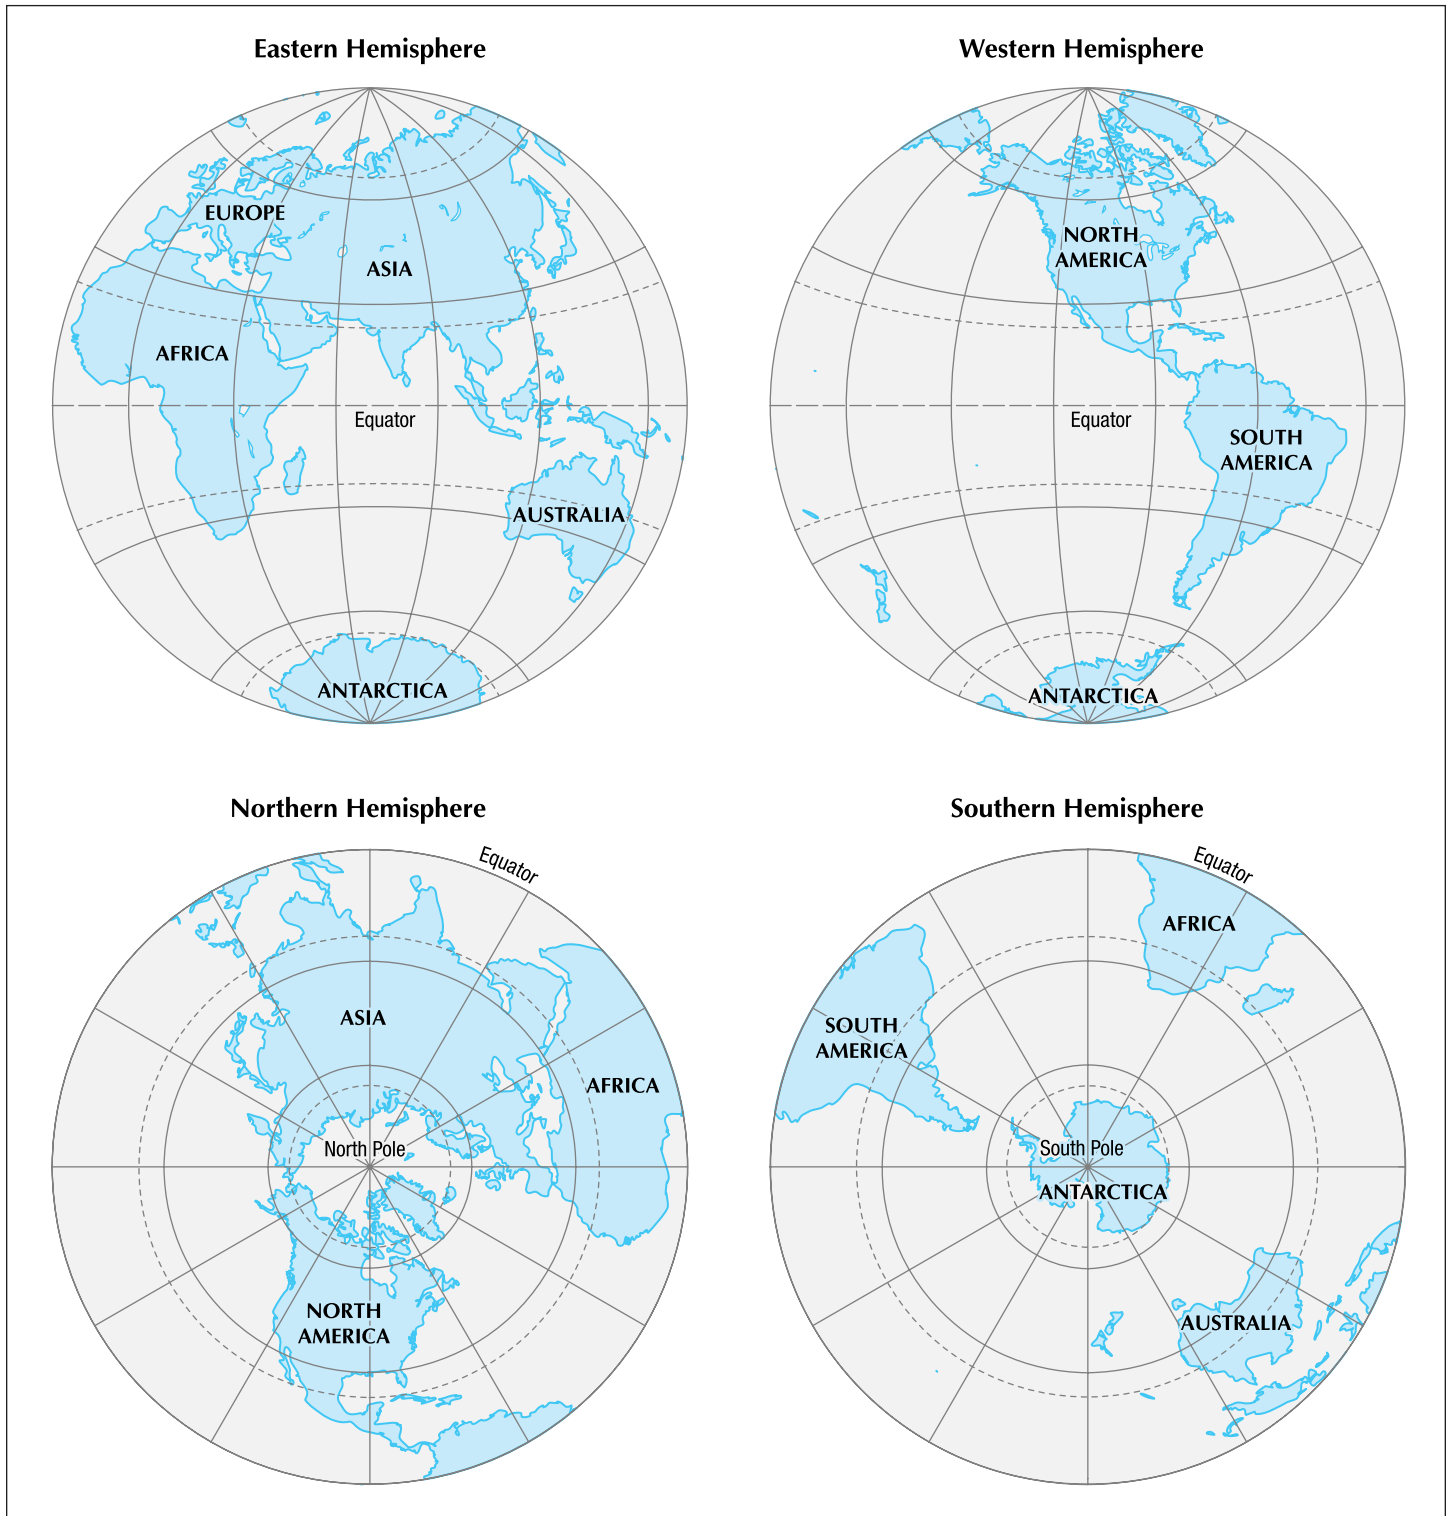

THE WORD *hemisphere* means "half a sphere." In geography, the term refers to half the Earth, and the enclosing boundary line of a hemisphere is a great circle. A space traveler viewing the Earth from a great distance will see only half the earth, a hemispheric perspective. This is true because the Earth is a sphere and only one side of the Earth can be seen in any one particular view.

Our only look at the entirety of the Earth's surface is through world maps. The map view of the world is important for that reason despite the fact that every map 1) is a scaled-down replica of the Earth, 2) presents a generalized view of the Earth's surface, and 3) is a distortion of the Earth's surface to varying degrees. There are an infinite number of possible hemispheric views of the Earth. When an observer looks directly at any particular point on the Earth's surface, a hemisphere is defined. However, there are a number of hemispheres that have special importance for the discriminating viewer. For instance, if the equator is the great circle enclosing a hemisphere, the viewer will be

seeing either the Northern Hemisphere or the Southern Hemisphere. In both cases, the center of the hemispheric view will be one of the poles. Viewing the Southern Hemisphere would show vast expanses of the southern oceans, interrupted by the southern extremes of South America and Africa, about half of AUSTRALIA, all of NEW ZEALAND, and a few scattered islands in the PACIFIC OCEAN. In the center of the view would be the geographical South Pole and the continent of ANTARCTICA, a true landmass covered by heavy sheets of ice. For example, South Pole station sits on ice that measures 8,000 ft (2,438 m) in thickness. The presence of a preponderance of water in the Southern Hemisphere has a great impact of the climate in this region. Since large water bodies do not heat up and cool as quickly as comparably sized land areas, the annual changes in temperature are much lower.

The view of the Northern Hemisphere is distinctly different. At the center of the view is the geographical North Pole, a point that is impossible to permanently mark on the surface because of the constant movement of the ice on the Arctic Ocean. South of the pole are the northern regions of the great landmasses of the northern hemisphere. Particularly imposing in this regard is the longitudinal sweep of Eurasia extending over 180 degrees of longitude. RUSSIA alone boasts of having 11 time zones. The northernmost reaches of North America are also prominent in this view, its land area bracketed by the ATLANTIC and PACIFIC oceans. The climatic impact of the presence of large land areas in the Northern Hemisphere is profound. The variability in annual temperatures is extreme in this region. It is not uncommon for areas within the continents of Eurasia and North America to have average winter temperature near 0 degrees F (-17.7 degrees C) and summer averages in the 70 and 80 degrees F (21 to 26 degrees C) range, temperature ranges not found in the southern hemisphere.

Familiar to everyone are the Eastern and Western Hemispheres. The two are separated by a great circle comprising two longitude lines, both running from pole to pole in opposite directions. The longitude line designated 0 degrees passes through Greenwich, England, and serves as one of the dividers between the two hemispheres. Its counterpart passes through the Pacific Ocean 180 degrees from the prime meridian. Hence, it is identified as longitude 180 degrees. An observer standing at any location along either of these lines is on the boundary between the eastern and western hemispheres. The prime meridian is the conventional starting point for assigning degree values to longitude lines.

The area west of the prime meridian to longitude 180 degrees is the Western Hemisphere. Conversely, the area to the east of the prime meridian is the Eastern Hemisphere. The longitude lines in both hemispheres are measured in degrees from the prime meridian. Time zones are also directly related to the 360 degrees of

longitude. The time of day increases east of the prime meridian one hour for every 15 degrees of longitude. On the other hand, the time of day decreases west of the prime meridian one hour for every 15 degrees of longitude. The longitude line at 180 degrees is identified as the INTERNATIONAL DATE LINE. A traveler cross-

ing the International Date Line in an easterly direction and entering the Western Hemisphere would then be in the previous day. On the other hand, travelers going from the Western Hemisphere into the Eastern Hemisphere would find themselves in the next day. Although 180 degrees longitude designates the International Date Line, the line is displaced to the west at one point in order to include the Aleutians and keep all of Alaska in the same day. Similarly, the line is displaced to the east in the southern Pacific Ocean to include the Cook Islands in the same day as Australia and New Zealand.

Two additional hemispheric views illustrate the land and water hemispheres. If a globe is oriented so that the Cook Islands in the South Pacific are in the center, the water hemisphere may be seen. This is the hemisphere that has the maximum amount of water in view. In addition to a few islands in the South Pacific, the only land areas visible are portions of Australia, Antarctica, and South America. All of New Zealand is seen. The water hemisphere perspective clearly illustrates the enormous extent of the Pacific Ocean.

If the globe is oriented with the country of Turkey in the center, then the land hemisphere comes into view. In this perspective the viewer is seeing the hemisphere that has the maximum land area. The entire continent of Africa is present as well as South Asia, Europe, and a large part of the Asian landmass to the east. In addition, the eastern portion of North America is in view.

## Himalayas

THE HIMALAYAN mountain region, located between INDIA and TIBET, has the world's highest peaks. It stretches from the INDUS RIVER in the west to the Brahmaputra in the east and has a length of 1,500 mi (2,414 km) and a width from 100 to 150 mi (161 to 241 km). Northwest of the Indus, the region of mountain ranges that extends to a junction with the Hindu Kush, south of the Pamir range, is known as Trans-

*The Himalayan mountain range, separating India and China, has the highest peaks in the world.*

Himalaya. Thus, the Himalayas represent the southern face of the great central elevated region—the plateau of Tibet—the northern face of which is buttressed by the Kunlun.

The physiography of the Himalayan mountain system can be classified into three parallel longitudinal zones:

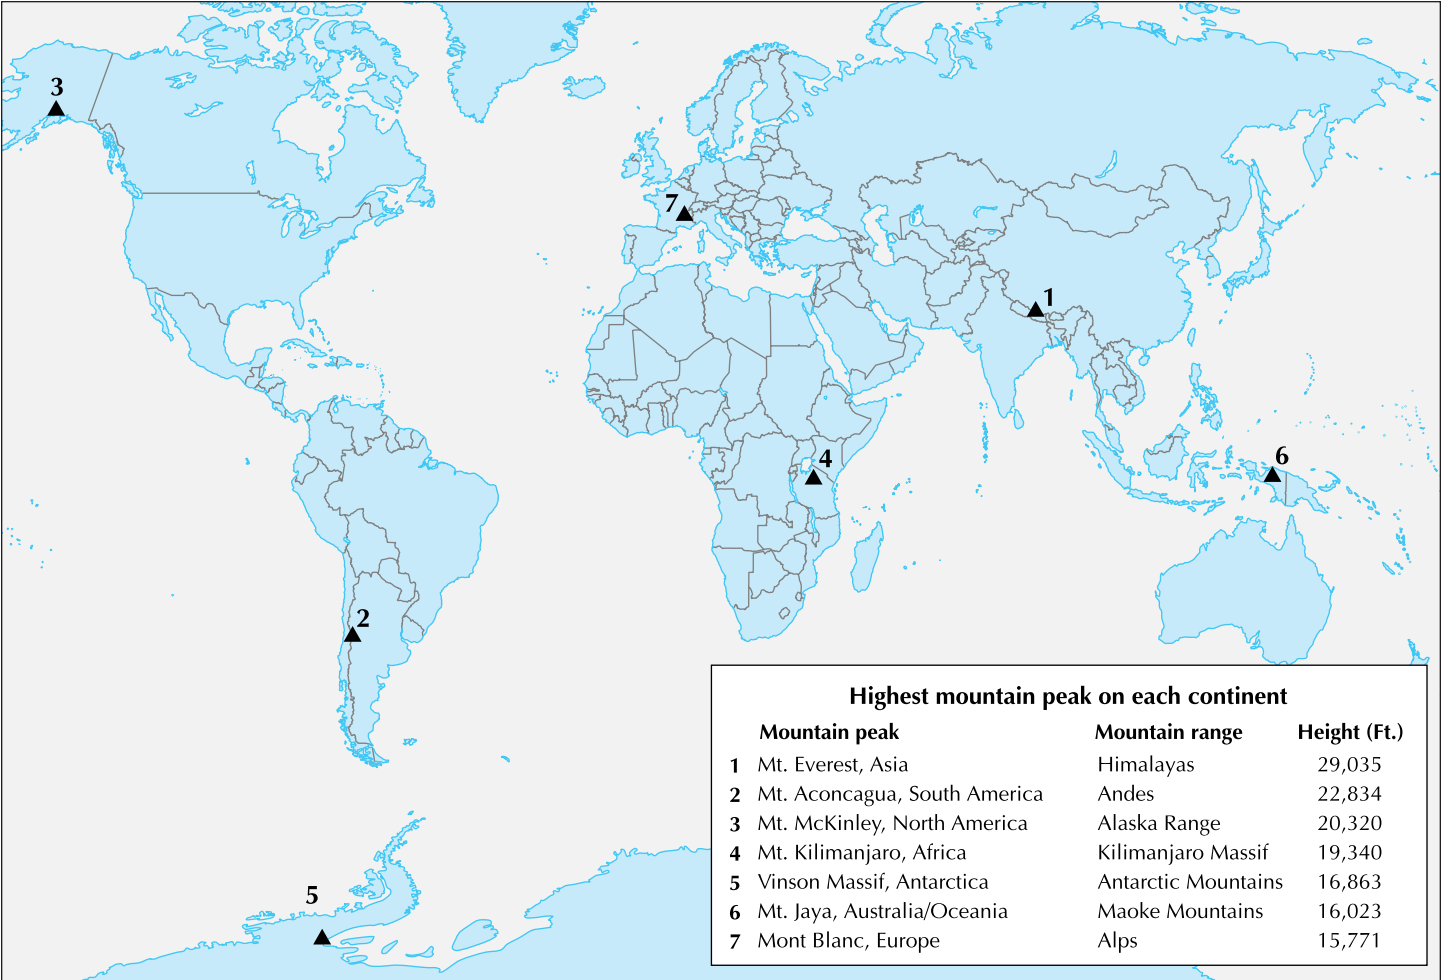

**The Great Himalayas.** The main ranges, which lie in the north, rise above the snow line and have an average elevation of 20,000 ft (6,096 m) above sea level. They include the highest peaks of EVEREST (29,035 ft or 8,850 m), K2 (Godwin Austen) (28,251 ft or 8,611 m) and Kangchenjunga (28,168 ft or 8,586 m).

**The Lesser Himalayas.** The middle ranges, which are closely related to and lie south of the Great Himalayas, form an intricate mountain system with an average height of 12,000 to 15,000 ft (3,657 m to 4,572 m) above sea level.

**The Outer Himalayas.** These comprise the Siwalik and other ranges, which lie between the Lesser Himalayas and the plains and have an average height of 3,000 to 4,000 ft (914 to 1,219 m) above sea level.

The above classification is a useful generalization but does not represent the peculiar and complex features of the Himalayan system. These include:

**The Great Northern Watershed.** On the north and northwest of Kashmir is the great water divide, which separates the Indus drainage area from that of the Yarkand and other rivers of Chinese Turkistan

(Sinkiang). It is not the great Himalayas but the Muztagh range which, with the Karakoram mountains, trends southward, forming a continuous mountain barrier and the true water divide west of the Tibetan plateau.

*Eastern Tibet.* The Tibetan plateau, or Chang, breaks up at about the meridian of latitude 92 degrees E, to the east of which the affluent of the Tsangpo (the Dihang and subsequently the Brahmaputra) drain from wild, rugged mountain slopes. In this region are

the sources of all major rivers of China and Myanmar (Burma).

It is now proved that Mount Everest, which appears from the Tibetan plateau as a single dominating peak, has no rival among Himalayan altitudes and is definitely the world's highest mountain. Everest was climbed by Sir Edmund Hillary and Tenzing Norgay in 1953. In Asia, there are 94 peaks exceeding 24,000 ft (7315 m); all but two are in the Himalayas or Karakoram.

Much of the Himalayan area is still very imperfectly known geologically. The general structure resembles that of the Alps, with huge overfolds and nappes; all the main horizons from Precambrian to recent appear to be represented. A very large number of rock groups have been distinguished, described, and given local names. It is certain that during Mesozoic times, the Himalayan area was occupied by the great geosyncline, which coincided with the Tethys Sea or ocean basin. The sediments laid down in the Tibetan section of this great basin constitute the Tibetan zone, in which fossiliferous beds of Paleozoic and Mesozoic ages differ entirely in facies from those farther south. The second or Himalayan zone, which comprises the Great and Lesser Himalayas, is composed chiefly of metamorphic rocks and sediments that are generally unfossiliferous. It is believed that the elevation of this central axis took place mainly in Eocene-Oligocene times and that during this phase the important nummulitic limestones were deposited in a series of basins, notably in Ladakh. The main orogeny would seem to have resulted from the northward movement of the ancient block that is now seen in peninsular India and that underlies the Indo-Gangetic plain. Continued movement in Miocene times folded the nummulitic limestones; the final phase of the mountain building came in post-Pliocene times and has scarcely yet ceased—as the Assam earthquake bears witness—and folded intensely the Pliocene Siwalik sediments of the southern flank of the Outer Himalayas.

The uplift of the Himalayas was a gradual process protracted over a very long period and had a very marked effect upon the scenery, the topography, and the river system. The last is not consequent upon the structure, but the principle rivers were of an age anterior to the tertiary earth movements and the drainage is spoken of as antecedent. During the slow process of uplift, folding, and faulting, the rivers were able to keep, for the most part, to their original courses, although their erosive power was increased because of increased gradients.

## Hindu Kush

HINDU KUSH (or Hindukush) is the main mountain range in the Central Asian state of AFGHANISTAN. Hindu Kush is the westernmost extension of the Pamir mountain, the Karakoram (K-2), and the western HIMALAYAS.

The origin of the term *Hindu Kush* (which translates as "Hindu Killer" or "Killer of Hindus") is a point of controversy among scholars. Three possibilities have been put forward in this context. One, the mountains concerned are tribute to Indian slaves who perished in the difficult mountainous terrain while being transported from India to slave markets of Central Asia. Two, the name is merely a corruption of Hindu Koh, the pre-Islamic name of the mountains that divided Hindu-populated southern Afghanistan from non-Hindu northern Afghanistan. The third possibility is that the name is a posited Avestan appellation meaning "water mountain."

The mountains of the Hindu Kush system diminish in height as they stretch in a westward direction. Toward the middle near Afghanistan's capital city Kabul, they extend from 14,763 to 19,685 ft (4,500 to 6,000 m); in the west, they attain heights of 11,482 to 13,123

ft (3,500 to 4,000 m). The average altitude of the Hindu Kush is about 14,700 ft (4,500 m). The Hindu Kush mountain range stretches about 600 mi (966 km) laterally, and its median north-south measurement is about 149 mi (240 km). Only about 373 mi (600 km) of the Hindu Kush system is called the Hindu Kush mountains. The rest of the system consists of numerous smaller mountain ranges, including the Salang, Koh-e-Baba, Koh-e-Paghman, Spin Ghar, Sian Koh, Suleiman, Selseleh-e-band-e-Turkistan, and Koh-e-Khwaja Mohammad. The western Safid Koh, Doshakh and the Siah Band are known as the Paropamisus by scholars of Central Asia. Three rivers flow from the Hindu Kush mountain range, namely the Helmand River, the Hari Rud, and the Kabul River that also provide water to major cities and regions of Afghanistan.

Huge caravans pass through high passes (*kotal*) transecting the mountains. The most important mountain pass in the Hindu Kush range is the Kotal-e-Salang, which links Kabul and points south to northern part of Afghanistan. Before the Salang road was constructed, the most famous passes in the Hindu Kush region were the Khyber Pass (3,369 ft or 1,027 m) and the Kotal-e-Lataband (8,199 ft or 2,499 m). The roads through the Salang and Tang-e-Gharu passes are critical strategic routes between Afghanistan and RUSSIA and other old Soviet republics.

The Hindu Kush is sparsely populated and inhabitants subsist year-round on livestock and crops. The Kalash people are one of the main inhabitant groups of Hindu Kush and claim to be descendants of Alexander the Great. They have their own distinctive laws, religion, and culture.

## hinterland

FROM THE GERMAN *umland*, a hinterland is inland territory behind and bordering a town on a coast or

river, or the backcountry extending from an inland town. In both cases, the hinterland generally falls under the legal and economic jurisdiction of the same state to which the city belongs. The hinterland supplies a city with food, fuel, raw materials and, in the modern period, labor. It also serves as a market for its manufactured goods and services. The flow of goods and services between the hinterland and city is facilitated by a communication infrastructure of roads, canals, and bridges.

The development of the hinterland is connected with the rise of cities, appearing first with ancient Mesopotamian ceremonial and administrative centers, whose population specialized in the maintenance of ritual, on the one hand, and trade or redistribution, on the other hand. Because the center's population was occupied primarily with non-food producing activities, it depended entirely for its food and fuel on its agricultural hinterland. The size and prosperity of a ceremonial and administrative city, therefore, depended on the agricultural productivity of its countryside, and tributary relationships were developed to control its resources.

A city that also engaged in long-distance trade, such as the polis of classical Greece (5th to 4th centuries B.C.E.), was less dependent on its hinterland if food could be obtained from farther afield. With expanding trade and a rise in population, the polis outstripped its hinterland's capacity for food production. The hinterland of classical Athens, Attica, was suited to the cultivation of olives and grapes, used in the production of olive oil and wine, which then were exchanged for grain from the Greek BLACK SEA colonies. Similarly, Quanzhou, a metropolitan port city in Southeast CHINA's Quannan region, served as one of the main trading centers in the South China Sea and Southeast Asia from 1000 to 1400. With Quanzhou's rapid expansion in the 11th and 12th centuries, its agriculturally weak backcountry, the Fujian hinterland, made the transition from food cultivation to that of cash crops such as lichee, sugarcane, and cotton and the manufacture of ceramics and metal products.

This commoditized city-hinterland relationship therefore served to include Greek and Chinese farmers on marginal arable lands in the international market. Additionally, premodern trading centers that lacked even agriculturally poor hinterlands, such as Timbuktu in West Africa or many of the early medieval coastal trading sites in northern Europe, either declined or were abandoned altogether when trade routes shifted away from these centers.

Even an agriculturally rich hinterland benefited from its relationship with the city. For example, the introduction of more animals to provision estates and pull the recently invented carriages of the elite in 17th- and 18th-century PARIS meant that more fodder had to be brought to the city. Hinterland peasants responded by planting fields with more oats and meadows with forage crops, delivering these products to the city and carting away the manure from urban stalls, which they would use in turn to fertilize nitrogen-poor fields. Paris basin hinterland farmers thus took advantage of the opportunities offered by economic changes in their core region and thus generally fared better than the outland French peasantry.

### MODERN ADAPTATIONS

In the 19th and 20th centuries, metropolitan hinterlands encountered further adaptations with the growth of long-distance transportation networks, communication, industrialization and banking. As with classical Athens, modern LONDON's south English hinterland is poorly equipped to feed the metropolis, but as a major financial center, London is able to import its food from distant mainland markets. Like Attica, London's lowland backcountry takes part in the long-distance market, using the revenues from its industries to purchase imports.

Third-world hinterlands, in contrast, suffer from slow technological development and poverty, resulting in the migration of the hinterland population to metropolises such as KOLKATA (CALCUTTA), which cannot support such a large population. A final example of a metropolitan hinterland is designated by the U.S. Census Bureau's term the Metropolitan Statistical Area (MSA), comprising three zones: the city, bounded by its corporate limits; an urbanized area contiguous to the city; and a nonurbanized area economically connected to the metropolis.

## historical geography

GEOGRAPHERS SEEK TO understand the world by examining spatial relationships. The types of questions they might ask are: Why are things located where they are? How are places different from each other? How are places like each other? How are places interconnected with each other? How do people affect their natural environment and how does the natural environment affect people? In many instances, the answers to these questions are related directly to what the world is like today.

For historical geographers, these questions are adapted to consider the role of time. For example, a historical geographer might ask questions such as: How did people, things, and landscape elements come to be located where they are? How did a place come to be like other places? How did it develop differently from other places? How have people been affected by the natural environment? How have they altered the environment as well? In short, historical geography might be described as the study of past places.

Some of the earliest attempts at what might be considered historical geography are rooted in ancient GREECE. Although typically identified as a historian, Herodotus has often been regarded by geographers as one of their own. Based upon his own extensive travels and keen observations, Herodotus developed a sophisticated understanding of how the processes of physical geography played out over extended periods of time, resulting in what was his contemporary landscape.

While individual travel and exploration aided in the development of the historical geographies of Herodotus, the expansion of Islam further developed the field of historical geography. By the mid-8th century C.E., religious conquests had brought northern Africa and the Iberian Peninsula under Islamic control. What transpired was an exchange of ideas between East and West. At the same time, Muslim concepts such as the use of the decimal system made their way into Europe, and Greek and Roman texts were translated into Arabic for the first time. Like the Greeks, Muslim scholars such as Al-Biruni incorporated the role of time within the processes of physical geography. In his study of India, Al-Biruni attempted to explain the formation and distribution of alluvial deposits, predating the development of similar ideas in Europe by centuries. Considered perhaps the most significant historical geographer of the medieval Muslim world, Ibn-Khaldun has been cited as the first to explicitly link the physical environment to human activity and culture

through time—thereby establishing the human-environment connection so crucial to the broader field of geography as well.

Nineteenth-century European historical geographers continued to study the relationship between humans and the natural environment with respect to time, but were furthered in their research by theoretical developments in the biological and social sciences. In 1859, Charles Darwin introduced the notion of natural descent in his historic volume, *The Origin of Species*. Drawing in part upon Thomas Malthus's ideas concerning population growth and the limitations of the natural environment, Darwin concluded that environments were capable of supporting a limited number of organisms and only those organisms best biologically suited to an environment would be able to remain in that environment and successfully reproduce. Those less well suited to the environment would ultimately face extinction because of competition from better adapted organisms.

### SOCIAL DARWINISM

Although Darwin himself did not specifically include humans within his understanding of evolutionary processes, other scholars like English philosopher Herbert Spencer would. Called social Darwinism, the work of Spencer (who coined the phrase “survival of the fittest”) drew parallels between human and animal societies and their relationships to the natural environment. Over time, humans had adapted to their natural environments.

But as historical geography would suggest, natural environments were always changing as well and humans would once again have to adapt or face extinction. Social Darwinism expanded these ideas to include not only the natural environment, but also the social environment. Only those people best adapted to the natural environment and how society had altered and organized itself would thrive and prosper while those not who were unsuccessful in their struggle for survival would eventually die out with time.

Evolutionary ideas like those of Darwin and Spencer were eventually incorporated into the work of historical geographers. German geographer Friedrich Ratzel has often been described as having been greatly influenced by the notion that human societies, like organisms, struggle to survive in specific natural environments. Ratzel suggested that states develop throughout history within the particular constraints of natural environmental resources, including space itself. When the population of a state begins to exceed or meet the ca-

capacity of these resources, it must expand its boundaries or be destined to go into a stage of decline and be threatened by more expansive and powerful states. Such expansionist theories of how the history of states was affected by the geography of a territory marked an advancement not only in historical geography, but likewise in the study of migration and geopolitics.

### HEARTLAND THEORY

Originally trained in the natural sciences like Ratzel, English geographer Halford J. MACKINDER also tied human culture and political organization through time to the environment. Through his heartland theory, Mackinder suggested that world history could be explained through an examination of the resources and accessibility of various natural environments. Prehistoric humans, he claimed migrated out of the “heartland” to other parts of the globe. Control of the strategic heartland then, had and would continue to dictate who held dominion over the rest of the world.

Just as Ratzel and Mackinder discussed historic diffusion of population and its impact on global politics past and present, European contributions to the field of historical geography diffused across the ATLANTIC OCEAN to the UNITED STATES as well. The influence of Ratzel is especially evident in the work of one of his American students: Ellen Churchill Semple. Although she served as the first female president of the Association of American Geographers in 1921, Semple is most typically remembered for her role as an environmental determinist.

Environmental determinism suggested that the cultural characteristics of a human society would largely evolve according to the physical geography of the group's home territory. As a result, some groups of people in the world were declared predisposed to immorality and laziness as a result of long-term exposure to tropical climatic conditions or because they lived in along mountain passes. Conversely, other groups, most notably those of Northern Europe, were deemed more successful due to the manner in which their physical environment challenged them and contributed to admirable cultural traits. Environmental determinism allowed for the integration of evolutionary history, culture, and physical geography.

Although much of Semple's work falls within the classification of environmental determinism, it also at times backs away from being absolutely deterministic. Semple suggested that while environmental conditions may influence people's actions and livelihoods, they cannot explicitly control people. Environmental condi-

tions may restrict or enable certain ways of life, but ultimately people make their own choices as to how to react to these situations. According to Semple, people did, however, tend to react to specific environments in predictable ways that could be described in terms of spatial patterns of behaviors and corresponding environments.

A contemporary of Semple, geologist Albert Perry Brigham, also began his career in historical geography by examining the role of environmental influences upon society. Later in his career, however, Brigham criticized fellow geologists and geographers who studied this link between humans and the environment, but failed to approach the matter scientifically. He criticized environmental determinists for creating broad generalizations concerning the effect of the environment upon culture that were not based upon scientific evidence but were rather descriptive accounts. Specifically, Brigham rejected their attempts to explain human society based solely upon climatic influences. The natural environment, he explained, was far too complex for geographers to be able to isolate singular environmental characteristics as the historical root cause of race, character, or culture.

Human adjustment to the physical environment through time continued as a primary area of focus after World War I with the work of Harlan H. Barrows. Through the development of the subfield of human ecology, Barrows redirected the emphasis of environmental determinists upon physical environmental controls toward a human-centered approach. Human ecology sought to understand the impact of humans upon the earth through time rather than merely the impact of the earth upon humans.

## CHOROLOGY

An even stronger rejection of environmental determinism in American geography was led by Carl O. SAUER in the 1920s. For Sauer, the primary purpose of geography should be chorology, or the study of areas. Rather than constrain geographers within the limits of environmental influences, geography should study places in terms of regular characteristics that tied them together. These regularities could then be analyzed to understand how areas differ as well as how they are interconnected.

For Sauer, one important way of classifying areas was the cultural landscape. Drawing upon both human ecology and chorology, geographers like Sauer examined how humans transformed the physical environment of the Earth to make it suitable for their own

needs. What remained was an imprint of human habitation: the cultural landscape. At times, practitioners of the cultural landscape approach to geography went so far as to challenge environmental determinist traditions by suggesting that human decision making was often a much greater determinant of location than were such physical geography components as climate, soils, and relief.

Chorology and the accompanying cultural landscape studies allowed for the explicit inclusion of history into geography. Cultural landscapes could be examined with regard to which people had lived in them and created them. From this trend emerged the work of geographers such as Derwent Whittlesey and his notions of sequent occupance. According to Whittlesey, a group of people that occupies a place leaves its cultural imprint upon the physical environment based upon its way of life. With the passage of time, preexisting groups must readapt the cultural landscape to meet their changing needs. Similarly, new groups to a location may also alter the preexisting cultural landscape to coincide with their society's needs and desires. What emerges in both instances is a succession of imprints upon the cultural landscape, each one in essence adding another layer to what the contemporary geographer sees. By working backward through time, a historical geographer could uncover each layer and come to understand how the past contributed to the creation of current cultural landscapes.

## METHODS AND RESOURCES

As the work of the early 20th-century scholars suggests, a key strength of historical geography lies within its ability to incorporate the notion of change. Historical geographers incorporate elements of the past to understand the present and future geographies. So how do historical geographers approach their work? What kinds of resources do they use?

Among the resources most used by historical geographers are archival documents, historic records of the past. Often these sources are stored by the government in national, state, and local archives; public and university libraries; as well as government offices. Examples of the type of information available in these locations include the original Federal Manuscript Census forms filled out over a century ago by hand; property ownership and land use records; natural resource inventories; and some of the primary tools of the trade for geographers—maps and photographs.

Maps and photographs have proven especially important for historical geographers who study the cul-

tural landscape. But equally important for them is the use of fieldwork that includes studying the landscapes as they are today. By looking at the material culture, or built environment, of a cultural landscape, the historical geographer may trace the elements back through history to understand what took place in the past.

For example, by studying the types of houses built or field patterns used, a historical geographer might be able to tie those elements back to another place in the world and in doing so uncover historic migration patterns. With that in mind, they might also attempt to relate the appearance of the cultural landscape to political, economic, or religious belief systems present in a society.

Fieldwork is also crucial for those historical geographers specializing in the transformation of the physical environment. After going into the field to take current measurements of physical phenomena such as river sediment discharge or inventory soil types, they can then compare those new measurements to those of the same places in past times. This process allows physical geographers to understand and chart historical change in the environment. Like cultural geographers, physical geographers may also combine fieldwork and archival documents in their work. Old maps, photographs, and even personal accounts of past environments can be used to fill in the gaps between time periods as well.

### HISTORICAL GEOGRAPHY TODAY

While the basic idea of historical geography as the study of past places remains today, the scale of those places and spatial relationships has grown considerably in more recent decades. One of the major areas of interest in historical geography today examines the process of globalization. Globalization describes how different places in the world are becoming more and more interconnected with each other every day. Many historical geographers are now interested in the history of geopolitics and the changes in world economies. By examining these systems at the largest scale possible, the global scale, historical geographers seek not only to understand how politics and economics impacted societies around the world in the past, but also to predict what new alliances and conflicts may arise in our future.

Migration studies are still vital to understanding the historical processes of globalization. In some instances, historical geographers examine migration patterns with the goal of trying to understand how countries such as the United States expanded as well as

how its settlers learned to adapt to new environmental challenges. While these historical geographers may focus on the progress of settlers and new nations, others may examine the issue of migration from the standpoint of the preexisting, or indigenous, population. Migration and settlement do not occur in empty space, but rather, in the case of colonialism, they affect the people who were already living in those places for centuries beforehand.

By understanding the changes that occurred with the development of colonialism centuries ago, historical geographers can hope to better explain the often difficult conflicts that emerge with the collapse of colonial empires in the 20th century.

This reexamination of colonialism from the perspective of native populations has also drawn attention to other groups whose stories have often been left untold. One area of historical geography that has grown substantially in more recent decades is one that focuses on feminist historical geography. Throughout history, women and men have often held different amounts of political, economic, and social power. Feminist historical geographers attempt to shed light on how these inequalities affected the way that women experienced historic events and places in dramatically different ways from men.

Modern technology has certainly aided in the practice of historical geography in more recent decades. With the development of cheaper and faster computing systems and the Internet, access to historic geographic data has grown substantially. Now, with only the click of a computer mouse, historical geographers can locate data sources on the Internet once available only on paper in archives. This turn to the digital world has also been reflected in the increasing use of geographic information systems (GIS) in historical geography. GIS often serves as a means for efficiently storing, retrieving, and analyzing historical spatial data that would have previously occupied thousands of printed volumes and taken thousands of hours to examine individually by hand. Understanding the past has certainly been aided by present technology.

Despite the centuries that have elapsed since the chronicles of Herodotus and Ibn-Khaldun, their work nonetheless still reflects ideas common to that of more contemporary geographers, even those using GIS. The goal of historical geography is not simply to provide a single snapshot image of past places, but rather, like these historic scholars, to come to understand how places of the past are related to those of today. Historical geography does not try to discover ultimate causes

or a single origin; rather, it recognizes that geographical relationships occur within a continuum of time—past, present, and future. Historical geographers attempt to reconstruct past places in the interest of understanding contemporary places and their potential impacts upon future ones.

## Hokkaidô Island

**NORTHERNMOST** OF the four main islands of JAPAN, Hokkaidô is surrounded by the Sea of Okhotsk to the north and east, the Sea of Japan to the west, and the PACIFIC OCEAN to the south. Its northern location and frigid ocean currents from the Sea of Okhotsk make Hokkaidô's climate considerably colder and drier than the rest of Japan; the island is known for its long winters. Hokkaidô is about the size of IRELAND, and almost square in shape, roughly 186 mi (300 km) on each side.

Japan and RUSSIA dispute territorial jurisdiction over four small islands to the north of Hokkaidô (Etorofu, Kunashiri, Habomai, and Shikotan). Japan had exercised control over these islands until the former Soviet Union occupied them at the end of World War II. (Jurisdiction over the much larger island of Sakhalin, or Karafuto as the Japanese call it, is split between Japan and Russia.) Hokkaidô was only fully incorpo-

rated into Japan in modern times. Until the 19th century, most of Ezo (the previous name for Hokkaidô) was a wilderness, home to the indigenous Ainu people. Today, the population of Ainu in Hokkaidô has dwindled to about 16,000 from death and assimilation. Many place names in Hokkaidô are in the Ainu language, including the prefecture's capital, Sapporo, and cities such as Kushiro and Muroran.

Japan's Meiji government renamed the island Hokkaidô in 1869, set national borders encompassing the entire island as part of Japan, and encouraged settlers to move north. Yet Hokkaidô remains sparsely populated by Japanese standards. Its population of about 5.7 million is less than 5 percent of Japan's overall population. On the other hand, Hokkaidô's area of 30,315 square mi (78,515 square km) makes it the second-largest island in Japan (after Honshû). The large area of Hokkaidô combined with its relatively small number of inhabitants yields a population density of 186 persons per square mi (72 persons per square km), only about one-fifth the national average.

The forests of Hokkaidô produce lumber and forest products, and the island is the largest source of coal in Japan, followed by southernmost major island of Kyûshû. The waters around Hokkaidô are rich sources of fish (including the local specialty of crab). Agriculture is another important part of the economy, and Hokkaidô provides much of Japan's food, including potatoes, onions, beans, wheat, and milk and other dairy products. Although the climate is far less suited to wet paddy field agriculture than lands to the south, new seed types permit the growing of rice, the single largest crop in Hokkaidô. In contrast to most of Japan, Hokkaidô has many dispersed farmsteads, with much larger farms, and employs far more draft animals. Parts of Hokkaidô resemble New England, with broad fields, rolling hills, and grazing cattle.

Tourism is another important part of the economy in Hokkaidô. The island is home to several large national parks, with clear deep lakes, snowy mountains, and unspoiled forests. The first Winter Olympics to be held outside Europe or the United States were hosted by Sapporo in 1972. Every February since 1950, Sapporo has also held an annual Snow Festival, featuring ice sculptures and snow statues; the festival attracted 2 million visitors in 2003.

Development of Hokkaidô has lagged behind the rest of Japan, in part because of the isolation of this northern territory and its separation from the main island of Honshû by long distances and the Tsugaru Strait. In 1988, the Seikan Tunnel linked Hokkaidô

with Honshû by underground rail, and the Bullet Train (Shinkansen) now has its northern terminus in Hokkaidô. Yet because of the distances involved, air travel remains a common route to Hokkaidô.

## homeland security

AS DEFINED BY the executive branch of the U.S. government, homeland security is "a concerted national effort to prevent terrorist attacks within the United States, reduce America's vulnerability to terrorism, and minimize the damage and recover from attacks that do occur" (July 2002 National Strategy for Homeland Security, issued by President George W. Bush).

In more simple terms, the primary end of homeland security is to secure the nation's borders. This is not to say, however, that the concept of homeland security is well defined or clear at all times. Much debate has occurred, particularly around the establishment of the Department of Homeland Security within the U.S. government, over the exact definition of homeland security and what types of both domestic and international issues are contained within such a concept. Further, the ultimate goal of homeland security is not always clear and may change over time, including at any one point in time prevention of terrorist attacks and/or minimization of harm that may occur as a result of such attacks. Both concepts seem to fall within the overall goal of "homeland security," but each has different organizational and resource requirements, and each impacts multiple governmental agencies and offices in a different manner.

Although the concept of homeland security has taken on a new sense of immediacy and familiarity, the idea of providing for homeland security or national security has a historical foundation within the UNITED STATES dating as far back (as an identifiable concept) as the Federalist papers. As noted by Harold Relyea, both John Jay and Alexander Hamilton wrote about "na-

tional security" in the Federalist papers, Hamilton suggesting that during war, "the energy of the Executive is the bulwark of the national security." As Relyea observes, however, the concept of national security truly took shape during the period between World War I and World War II, when the idea of a need for a unified, national interest in securing the nation and a national approach to foreign policy was blossoming.

The concept of homeland security has become most well known within the context of the post-September 11 landscape of the American government. Following the terrorist events, on October 8, 2001, through an executive order, Bush established the Office of Homeland Security to carry out this national strategy, appointing former Pennsylvania Governor Tom Ridge as assistant to the president for Homeland Security. In the immediate aftermath of September 11, the concept of homeland security was a symbolic, idealistic belief in the need to provide security for the nation. Over time, however, the concept took shape in the form of concrete policy decisions issued by Congress and the president himself. Ultimately, in June 2002, Bush sought to make homeland security a permanent, established part of the federal government, proposing the creation of both a Department of Homeland Security and an executive office of the president devoted to certain aspects of homeland security, namely the National Office for Combating Terrorism, the most extensive reorganization of the federal government since the Harry Truman administration of the 1940s.

In July 2002, Bush released a National Strategy for Homeland Security outlining his vision for securing homeland security and the role that the new department was to play. This strategy outlines the definition for homeland security provided above and identifies four foundations intended to help maintain homeland security: law, science and technology, information sharing and systems, and international cooperation. Each area or foundation is given a role in providing homeland security in the post-September 11 arena. As these foundations indicate, providing for homeland security impacts more than simply the federal-level agencies. It is a highly decentralized mission, which impacts both the federal and the state government, from the national down to the local level. By recent estimates, nearly 70 federal agencies alone are involved in some aspect of homeland security, and one can imagine hundreds of state and local agencies and offices likewise impacted.

## Honduras

**Map Page** 1136 **Area** 43,278 square mi (112,090 square km) **Population** 6,669,789 **Capital** Tegucigalpa **Highest Point** 9,416 ft (2,870 m) **Lowest Point** 0 m **GDP per capita** \$2,600 **Primary Natural Resources** timber, gold, silver, copper, lead, zinc.

Honduras is located right in the heart of Central America, sharing borders with EL SALVADOR, NICARAGUA, and GUATEMALA. Most of the people are considered mestizos, or of a mixed heritage of white and Amerindian. The country's area includes the three Caribbean islands ceded to the country by the UNITED STATES in 1971, Roatan, Utila, and Guaranja. Honduras's topography is varied, with mostly highlands through the central part of the country, flanked by coastal, tropical coasts. Currently, 7.7 percent of the country is preserved by the government, and includes tropical rainforest and fragile coastland. Education at the primary level is free and compulsory; the literacy rate for both men and women is about 30 percent. Healthcare is very poor, and conditions are some of the worst in the Western Hemisphere. The life expectancy is about 67 years old.

Like its neighbors, Honduras possesses an enormous amount of natural resources in its rainforests and coastline. One of the most precious of these resources, and also the source of notorious conflicts with Nicaragua, is the Miskito coast of the southern portion of the Honduran Caribbean coast. This preserved forest, which is home to the Miskito indigenous group, is under partial jurisdiction of the Honduran govern-

ment. Home to thousands of fish and bird species, this untouched "biogem" presents an opportunity for the country to develop sustainable tourism in its lesser developed regions.

Another natural resource of Honduras, and likewise a source of contention with its neighbors, is the Gulf of Fonseca, which is located on the western coast. El Salvador and Nicaragua also share a border with this gulf, creating a dynamic of competition and culpability for aquaculture and pollution. Shrimp farming has proliferated in the gulf, creating environmental degradation for native wild species as well as tremendous coastal development. Since three countries share the gulf, conflicts often arise when fishing harvests are diminished; addressing problems of over-fishing and water pollution to alleviate small harvests becomes a game of finger pointing.

Political life in Honduras has been tenuous and complex. Original settlements of the warlike Lencas and Jicaques were taken over by Spanish colonizing forces in 1524. Despite declaring its independence in 1838, Honduras's government has still suffered economic and political forces, such as America's United Fruit Company, that lie outside its boundaries. United Fruit Company had a long presence in the Caribbean and was notorious for its enslaving conditions of Honduran workers whose lands were monopolized and whose livelihoods were at the mercy of the huge corporation. The company has since left the country and been broken up, but present-day fruit distributors, like Dole and Del Monte, provide hauntingly familiar dynamics between their mass production and local communities.

## Hong Kong

HONG KONG IS A FORMER British colony that returned to the People's Republic of CHINA on June 30, 1997, and is now officially the Hong Kong Special Administrative Region. Hong Kong consists of the island of Hong Kong and about 200 islands and the New Ter-

ritories that are on Kowloon Peninsula on the mainland. Hong Kong has a tropical monsoon climate. Its winters are cool and humid. Rain falls from spring through the summer, and autumn is warm and sunny.

Hong Kong covers an area of 421 square mi (1,092 square km) and has a population of 7,394,170 (2003). Its highest point is Tai Mo Shan at 3,142 ft (958 m) and its lowest point is the South China Sea at 0 m. The gross domestic product per capita is \$26,000 (2002).

Since the end of British rule, Hong Kong has functioned under the “one country, two systems” relationship with China. According to the Joint Declaration in 1984 reached by Britain and China, Hong Kong, as a special administrative region of China, would have autonomy in its internal affairs and its economic system for 50 years after the end of colonial rule. Hong Kong is a limited democracy that is governed according to the Basic Law approved in 1990 by the National People’s Congress. The chief executive is the head of government who is advised by an executive council. Laws are made by the Legislative Council, which is a unicameral body of 30 seats indirectly elected, 24 directly elected seats, and 6 chosen by an 800-member election committee.

Hong Kong began as a small fishing community and a den for smugglers that was of little significance in its early history. Hong Kong was part of a trading network that centered around Canton in the 18th and early 19th centuries. Great Britain became interested in Hong Kong as a commercial base and as a colony for its deepwater harbor. In 1841, the island of Hong Kong was occupied by British forces during the Opium War. By the Treaty of Nanjing in 1842, China ceded the island of Hong Kong to Britain “in perpetuity.” In 1860, after the Second Opium War, Britain obtained a 99-year lease on the Kowloon Peninsula, which became the New Territories. Throughout the 19th century, the development of Hong Kong from a barren island to a major Asian port was made possible by cooperation between British administrators and a Chinese business elite.

In 1912, Hong Kong experienced a major influx of refugees who escaped the turmoil in China following the overthrow of the Qing Dynasty, increasing the population from 600,000 in 1920 to 1.6 million in 1941. On December 7, 1941, Japan attacked Hong Kong and occupied it for more than three years, reducing the population to 600,000. With World War II behind them, the people of Hong Kong expressed a desire to participate more in the political process. After the communist takeover in China in 1949, many Hong Kong

residents were worried about their future. Hong Kong was again inundated with about 700,000 refugees who escaped from the civil war on the mainland. However, there came to be a quiet understanding between Mao Zedong and the British that China would maintain the status quo because of trade benefits Hong Kong provided and the \$5,000 in rent that British paid for the lease in the New Territories.

Between 1971 and 1982, Hong Kong underwent major reforms in housing, education, police, health care, and infrastructure through the leadership of Governor Sir Murray MacLehose. Beginning in 1982, British Prime Minister Margaret Thatcher met with Chinese Premier Deng Xiaoping to discuss Hong Kong’s future. In 1984, both countries issued the Joint Declaration specifying Hong Kong’s return to the People’s Republic of China in 1997 as a special administrative region. The suppression of student protesters at Tiananmen Square caused alarm among many residents of Hong Kong about their relationship with BEIJING. In 1990, the Basic Law, which serves as Hong Kong’s constitution was passed by the National People’s Congress.

Hong Kong’s population is generally homogeneous; 95 percent is Chinese and the remainder is mostly Indian and European. Cantonese Chinese and English serve as the official languages for the territory.

Hong Kong has one of the most developed economies in the world. From its beginnings as a free port, Hong Kong relies almost exclusively on international trade. Having little natural resources, Hong Kong must import its food and raw materials. Hong Kong has extensive investment trade and investment ties with China.

## Horn of Africa

THE PENINSULA OF NORTHEAST Africa is called the Horn of Africa. It lies opposite of the southern Arabian Peninsula. This area is also known as the Somali

Peninsula because within it lies the countries of SOMALIA and eastern ETHIOPIA. It is the easternmost extension of the African continent separating the Gulf of Aden from the INDIAN OCEAN. It is sometimes also used as a name for the entire region of countries in northeast Africa including ERITREA, DJIBOUTI, Ethiopia, and Somalia and sometimes even including parts of SUDAN and KENYA. The Horn of Africa also alludes to the shape of this area because it sticks out like that of a rhinoceros horn from the continent of Africa.

The Horn of Africa is made up of a wedge of land that is cut north to south by two great geographical features: the NILE RIVER Valley and the Great RIFT VALLEY. Between these two features are high plateaus and rugged volcanic mountains. West of the White Nile River spans the great and vast SAHARA DESERT. The Great Rift Valley rises to just over 1 mi (1.6 km) above sea level in central Ethiopia and then drops well below sea level in the Danakil (or Dallol) Depression. Some places in the depression are over 328 ft (100 m) below sea level making it one of the lowest places on Earth not covered in water.

It is known as one of the most inhospitable places on Earth because the landscape is sand and volcanic rock. Much of the area is still active volcanically and tends to have intermittent earthquakes. It is also the hottest place on earth with temperatures that can reach up to 145 degrees F (63 degrees C) in the sun. From the coast of Eritrea, the Danakil Depression drops even further into the depths of the Red Sea.

The coastal lowlands along the Gulf of Aden and the Red Sea are mainly desert, as is most of Eritrea and northern Sudan. Southern Sudan is covered in savanna. Much of Ethiopia is covered in highlands that were once thickly forested. Over millennia, this area suffered from deforestation but there are still some small isolated areas of tropical forest. Much of this area could be used for agriculture but has yet to be truly developed. All of the countries of the Horn have petroleum, natural gas, gold, silver, copper, and iron ore but not much of this has really been developed either.

The main reason this area is important is that the Horn of Africa commands the Red Sea and the northwestern portion of the Indian Ocean. There are many good ports on both sides of the Horn. Ships traveling in the area headed for the suez canal and the Mediterranean from Asia, the Persian Gulf, and East Africa all have to navigate through the narrow waterway at BAB EL MANDEB, the entrance to the Red Sea. Thus, its importance is not only geographical but political as well. The people of the Horn subsist in vastly different styles

ranging from those that are hunter-gatherers and fishermen to nomads and farmers to industrial workers and more urban modern professions.

Most of the people of the Horn are farmers who still use draft animals to turn the land. Per capita income, literacy, and life expectancy are among the lowest in the world on the Horn. There are over 200 languages and dialects spoken over the Horn. There are even more ethnic groups that are further broken down into tribes and clans many of these who have deeply divided loyalties. There has almost always been conflict on the Horn for some reason or another, whether if be for political, ethnic, economic, or religious purposes and it does not look like that will change any time soon.

## horst

**HORST** IS THE German word for a high-nesting area for a bird, so the term infers a high elevation. Early geomorphologists fittingly applied the German word to a fault block mountain range. The faulting and vertical displacement is due to tension stresses in the crust. Tension causes crustal rock to spread apart and break to form steeply inclined normal faults.

The fault lines are normal to the direction of spreading and parallel to each other at the surface, but their planes dip away from each other beneath the surface. A horst is left standing either by sinking of the crust on either side of a pair of normal faults or by physical lifting of a crustal block between the faults. Geomorphologists often use the German word *graben* (which means "trench" or "grave") for the low-lying block between two horsts.

Horsts have either symmetrical or asymmetrical profiles. Equal rates of vertical movement along the parallel faults produce a symmetrical profile. Horsts of this sort may have flatlike tops, but they are more likely in various stages of erosion. Horsts have asym-

metric (tilted) profiles when the vertical movement is along only one of the bounding faults. The resulting mountain has a steep escarpment on one side and a gentle back slope on the opposite side. The Sierra Nevada of CALIFORNIA are a classic example of a asymmetrical fault block mountains; their steep eastern escarpment faces NEVADA and the gentler western back slope faces California's Central Valley.

Horsts (ranges) in combination with grabbens (basins) form a basin-and-range topography; Nevada is in the middle of this terrain type, which extends into IDAHO, OREGON, California, UTAH, ARIZONA, and NEW MEXICO as well as northern MEXICO. Countless horsts interrupt the landscape of the region. For example, California's Owens Valley (a graben) separates the Sierra Nevada from the White Mountains (also a horst). Another example is the Panamint Mountains and Armagosa Mountains; they align on either side of Death Valley. Countless horsts occur in other parts of the world, wherever normal faulting has occurred. The Vosges Mountains of France, the Harz Mountains of GERMANY, the island country of TAIWAN, and several highland ranges of KENYA and ETHIOPIA in eastern Africa are horsts. The SINAI PENINSULA between water-filled grabben of the Gulfs of Suez and Aqaba is another prominent example.

## Huang (Yellow) River

THE YELLOW RIVER, called the Huáng Hé by the Chinese, is the second longest river in CHINA reaching 5,500 km (3,000 mi), second only to the CHANGJIANG (Yangzi River). The regions to the north and south of the Huang River are called, respectively, the Hebei (north) and Henan (south). The chief tributaries of the Huang River are the Wei and Fen Rivers. The Huang River originates in the Yekuzonglie basin at an elevation of 4,500 m (13,500 ft) in the Bayan Kera Mountains and flows in an easterly direction through nine

regions: Qinghai, Sichuan, Gansu, Ningxia, Inner Mongolia, Shanxi, Shaanxi, Henan, and Shandong, where it finally reaches the Bohai Sea. The Huang River has made at least five major direction changes from 602 B.C.E. to today. It is believed that the most devastating direction change occurred in 1194, killing hundreds of thousands of Chinese and destroying the economy. The latest direction change occurred from 1855 to 1897, resulting in the current easterly flow.

The Huang River gets its name from its color caused by the sediment carried by the flow. Large-scale erosion occurring in the northern regions continues to be a problem for the Chinese government, as it increases the danger level of the river through buildup of sediment farther downstream. In fact, the Huang River remains the most dangerous river in China.

The Huang River basin is where Chinese civilization originates. Some historians believe this is because of a unique land structure found only here and nowhere else in the world. The land structure is called Tai Yuan, meaning a table land on a plateau. What is left on the Tai Yuan gives researchers an idea of the landscape prior to it being carved up by the river. Researchers explain that these land structures were ideal for agricultural development, community activities, and unrestricted movement because it is believed that the current Tai Yuans were once much closer together, if not a single unit.

A large problem associated with the Huang River is the continuous flooding, due in large part to the heavy sediment that is carried off by erosion and left to rest in the lower regions, causing the flow to slow and preventing the river from reaching the Bohai Sea. The river, on an annual basis, fails to reach the sea one-third of the time, which is largely attributed to an increase in ciphering off of water by families, factories, and farmers and, of course, the large amount of sediment left behind in the lower regions from erosion in the upper regions. In 1955, the Upper and Middle Huang River Administration Bureau was created under the Huang River Conservancy Commission to initiate soil conservancy and sediment reduction.

Silt deposition has created large problems for certain areas of the Huang River. In some areas the river bed is elevated 60 to 70 ft (18 to 21 m) above the surrounding towns. Since the 2nd century B.C.E., the Huang River has broken the levees some 1,500 times, inundating the surrounding towns. For example, in 1642 the levees broke, killing some 300,000 people. And again in 1938, the Chinese government decided to flood the levees in an attempt to stop the Japanese in-

vaders, resulting in the deaths of 900,000 Japanese and Chinese combined.

Currently, the Chinese government has undertaken a project that rivals no other water project in the world: to transport water from the overflowing Changjiang in the south to the Huang River in the north. Three canals will deliver the water to the drier regions at a distance of 750 mi (1,250 km). A conservative cost estimate for this project is \$30 billion; however, that can easily reach up to \$60 billion or higher as the routes that the government wants to take are dangerous and, in some cases, require almost impossible engineering feats.

Work has begun on two of the south-north canals and engineers from the east are working on an ancient waterway called the GRAND CANAL. These two canals are expected to serve a population of 20 million, a population that must ration water until the project is built. The most expensive canal is the third, which is planned to deliver water from the higher regions of the Changjiang to the higher regions of the Huang through rugged mountains. This water will provide farmers of the most important agricultural regions the resources to adequately produce corn, sorghum, winter wheat, vegetables, and cotton.

Finally, it must also be noted that the canal project put forward by the Chinese government is highly controversial because of the nature of the project, the amount of money needed to finance it, and the impact it will have on the surrounding environment.

## Hudson River

"THE RIVER THAT Flows Both Ways" is located between Lake Tear of the Clouds and the southern tip of Manhattan in NEW YORK. It flows 315 mi (507 km) and empties into the ATLANTIC OCEAN. Its low and high

tides, along with its salty water, account for the river's bidirectional water flow.

The Lower Hudson River (an estuary) is the dwelling place of a wide variety of plants and animals. Tidal marshes (called Meadowlands) filter the water that passes through them, and over 200 species of fish inhabit the river. The Hudson is located on the Atlantic Flyway and provides food to birds migrating in this north-south corridor. Its base of limestone rock enhances the river's ability to manage common pollution.

In 1609, the Englishman Henry Hudson, captaining a Dutch ship, stumbled upon the river in his search for the legendary Northwest Passage. At the time, native tribes already occupied the 4 million acres of the Hudson Valley, which expands from its narrow watercourse from below Waterford until the approaches to the Palisades Cliffs in NEW JERSEY, across the river from New York City. The indigenous population called the valley's river, Mukheakantuk, which means "Great Water in Constant Motion," or "The River That Flows Two Ways." The Dutch first named it "River of the Prince Mauritius"; it was not until 1664 that the English named it after Henry Hudson.

During the American Revolutionary War, the Hudson River facilitated the transportation of troops and supplies from the port of New York to military campaigns taking place to the north. The completion of the Erie Canal in 1825 enabled water transportation to cross upstate New York, all the way to Lake ERIE, and from there, farther into the Great Lakes region. The canal system made the Hudson River viable for significant trade along the Atlantic and deep into the American heartland.

The Hudson's visual landscape found wide application by artists seeking a characteristic backdrop for their paintings depicting the lush New World. The first major artist known for his sketches inspired by the Hudson River Valley was Thomas Cole. His sketches became an inspiration to other artists, and the Hudson River School of Painting was formed. Today, these works of art are located in the Historical Society of Newburgh Bay and the Highlands in Newburgh, New York.

After the Revolutionary War, ferries became popular for transporting citizens across the river. But river cruises and ferry transportation in general declined with the increase in pollution, which rose to dangerous levels in the mid-20th century. Once the source of drinking water to many cities, the Hudson River experienced a time when companies and residents dumped anything from caustic chemicals to motor oil to dis-

carded food into it, bringing about levels of toxic pollution that rose to a level lethal to humans who swam in it. Over the years, actions from residents and the government have been successful in the cleanup and restoration of the river. One of the most recent actions was an Act of Congress in 1996, which designated the Hudson River Valley National Heritage Area.

Despite the river's ghastly polluted past, the Hudson River is now in better condition than many Atlantic Coast estuaries. Its cruises have become popular again. The George Washington and Tappan Zee bridges span the river and provide a view of the Palisades cliffs for its travelers. The Metro-North Hudson River line railroad serves as a commuter line and as a means of transportation for residents and visitors to visit shops in many valley cities, including New York itself. As a geographic route to New York City, the hijacker piloting one of the planes that struck Manhattan on September 11, 2001, used the river to navigate the plane south from the Boston area.

## human-environment relationships

THE ENVIRONMENTAL approach in geography, history, anthropology, psychology, and other spheres of humanitarian thought remains one of the most alluring and unequivocal since its origin in ancient times. At the beginning of the 21st century, interdisciplinary studies of cultural history using contemporary methods of instrumental analysis are often bringing scientists to the necessity of taking environmental issues into account when conceptualizing local peculiarities of cultural evolution. As a result, an impressive variety of theories and concepts has been elaborated in the framework of scientific and humanitarian thought during the second half of the 20th century.

Trying to navigate in this boundless theoretical space, an inquisitive researcher inevitably faces the ne-

cessity to create some kind of exploratory structure encompassing these approaches and notions. Here, comprehension of human agency in natural environment evolution has been chosen as the main criterion of examination of human-nature interaction. On this base, three main directions of environmental thought development can be distinguished in contemporary humanitarian and scientific thought.

One of them, known as geographical determinism, concentrates on the environmental impact on human history. The second, concerning human agency in nature development, became popular alongside global reconsideration of the human role in the universe, which took place at the time of the scientific revolution. Adepts of a third direction tend to interpret human-environment interaction as an integrated system, all elements of which are of equal importance and are engaged in complicated reciprocal influence.

### GEOGRAPHICAL DETERMINISM

Geographical determinism comes from the "man as sufferer" paradigm in the adaptation concept. Interpretation of a human being as a passive sufferer originated in ancient natural philosophy. Since its very beginnings, the human being was regarded as a creature deeply dependent on its natural habitat.

As early as at the middle of 4th century B.C.E., geographic determinism had been designed as a specific direction of philosophic thought with at least two extreme schools: one of climatic psychology and another of climatic ethnology. Later climatic astrology also originated.

The Enlightenment ideology reconsidered these ideas about total human dependence on nature and elaborated the wide circle of geographically and climatically deterministic theories (C. Montesquieu, L. Mechnikov, E. Semple, E. Huntington, E. Reclus).

At the second half of the 20th century, this idea was treated in the framework of the adaptation concept, which is interpreted by representatives of "new" (L. Binford) and behavioral (B. Schiffer) archaeology, environmental psychology (A. Bell), and phenomenological (T. Ingold) and actional (E. Markaryan) approaches to culture studies as phenomena inherent for an active and creative human being.

In Soviet science, most attention was paid to the biological aspects of adaptation, with an emphasis on the human capacity to fit the requirements of natural environment.

At the end of 20th century, adaptive reaction has become the subject of special attention. As a result,

general theory of stresses and ecological stress concept were elaborated (P. Bell). To identify the possible character of human beings and human society in response to natural environmental changes, the concept of social and ecological resilience was introduced (A. Neil).

Thus, the idea of humans as nature modifiers and creators came to be. Roots of the idea of human domination over nature are traced as early as the Enlightenment times, when the human ability to solve rationally all his or her vital tasks was declared for the first time (T. Hobbes, C. Linney).

### ECOLOGICAL CRISIS

Along with the beginning of industrial development and the origin of first ecological crisis at the middle of 19th century, scientists study the results of a transforming impact from human activity on the natural environment (J. Marsh, A. Voeikov). During the 20th century, the idea of humans as nature-creators was conceptualized in the context theories of cultural (O. Schluter, C. Sauer) and anthropogenic (in Soviet science) landscape, and the notion of landscape as series of sequent occupancies (D. Whittlesey).

In frameworks of postmodern methodology, this idea is conceptualized in the idea of landscape as artifact, based on two ideas (T. Darvill, P. Criado Boado). One of them is that landscape should be interpreted as a mental image, which could not exist without human beings who elaborate it. At the same time, humans consciously and purposefully form their geographical environment, and their decisions about living space ordering are deeply motivated by their vital needs. Consequent application of these postulates inevitably results in partial or total negation of the natural landscape existence.

This idea has become the starting point for the theory of human ecodynamics, which concerns the analysis of changes made by humans in the landscape in a long-lasting perspective.

In spite of principal differences in theoretical backgrounds of the “human as nature-creator” concept, they incorrectly tend to date the beginning of the human impact on nature with the origin of agriculture and farming. Thus, the possibility of hunters and gatherers substantially reshaping their landscape is practically excluded or regarded as a minimal and non-permanent one, displayed only in connection with so-called secondary landscape components.

There is also the idea of mutual creativity in human-environment interaction. The process of formation of so-called integral direction of man-environment

interpretation is long and ambiguous. These ideas, originating for the first time in ancient natural philosophy, obtained theoretical scientific background during the second half of the 19th century (J. Raskin, K. Ritter).

The fundamental theoretical background for this idea was elaborated during the late 19th and early 20th centuries in the framework of anthropogeography (F. Ratzel) and biosphere theory (V. Vernadsky). The traditional variant of anthropogeography envisages attention to all spheres of human culture and to humanity itself, taken as social and biological creature (F. Ratzel, A. Hettner, A. Grigorev, A. Borzov). At the same time, some researchers proposed to limit their subject field by the phenomena, which directly and materially display themselves in the landscape (O. Schluter, O. Brun) or by the human being as an organic form of life (W. Davis).

### AN EMPIRIC BACKGROUND

Intensive deepening of our knowledge about climate, relief, flora, and fauna and their chronological and spatial distribution, which took place at the middle of the 20th century thanks to active development of environmental archaeology, geoarchaeology, and paleogeography, has created an empiric background for theoretical conceptualization of the “man in nature” idea in Western European and American archaeology, prehistory, and paleogeography. In Soviet science, such ideas were reflected in research activity of proponents of the so-called paleoenvironmental approach to prehistoric studies (S. Bibikov).

As a result, at the beginning of the 21st century, one can trace the gradual growth of popularity of the idea of mutual and interdependent evolution of nature and society. A specific form of its interpretation is proposed by representatives of mainly postmodern directions of contemporary geography, scholars who have introduced a wide spectrum of variants of landscape understanding.

MECHNIKOV NATIONAL UNIVERSITY, UKRAINE

## human geography

HUMAN GEOGRAPHY FOCUSES on interpreting and describing the various ways in which humans in all places and cultures adapt to and possibly modify their natural geographic environments. At the local or national scale, human geographers look at how economic, political, and cultural issues are related to spatial organization in different parts of the planet. How have humans modified topography, changed microclimates developed and changed rivers, lakes, and even coastlines?

Human geography is distinguished from PHYSICAL GEOGRAPHY by its focus on human activities regardless of specific cultures. Changes related to different cultures or social systems is the realm of CULTURAL GEOGRAPHY.

### REGIONAL AND GLOBAL PATTERNS

Today, human geography also looks at regional and global patterns. Because of the spread of modern technology, humans today can make changes in the natural environment at a much faster rate and much grander scale than at any other time in human history. In addition, conflicts such as war can cause immediate and widespread environmental damage, such as the oil fires and spills during the various conflicts in IRAQ and KUWAIT or the widespread killing of wildlife in various African conflicts. The extent of environmental degradation and pollution in the former Soviet Union and the demise of the ARAL SEA are other examples of human-created changes in geography. Like physical geography, human geography is divided into a wide range of subtopics. These include economics, transportation, cultural geography, urban geography, and political geography. For example, human geography, when dealing with environmental issues, is not limited to natural dynamics but also takes into account the fact that there are distinct social, economic, and political environments.

The problems dealt with by human geography have varied over the course of time. In addition, new models and technical abilities affect how problems in the human-physical environment are approached. Given the diversity of philosophies and models for the description and analysis of human-environment interaction, it would be more appropriate to speak of a plurality of human geographies rather than one single human geography.

In 1992, David N. Livingstone noted different approaches to the discipline. According to this English geographer, the whole set of problems, subjects, and concepts that have developed over time have come to form part of this tradition and to be called human geography. From the time of the explorers to the drawing of maps, from the days of proposals for the study of industrial locations to the study of the distribution of wealth throughout the world, or the spaces constructed by "gay" communities or "okupas," up to the time of the survey of the surface of the Earth with remote sensors and cartography based on GEOGRAPHICAL INFORMATION SYSTEMS (GIS)—all of this has come to be a part of the human geography tradition and to distinguish it from the type of history and cultural or social and political analyses and description developed by other disciplines.

It is possible to distinguish four significant events that help to understand how different problems and subjects have become defined as human geography. These events were: 1) the formal recognition of modern geography (1870–1920); 2) the development of pragmatic perspectives (1950s); 3) the manifestation of radical and critical views (1970s); and 4) the development of what has been termed a postmodern approach along with more traditional cultural geographies (1980s and 1990s).

### FORMAL RECOGNITION (1870–1920)

Human geographies developed in most European countries were influenced by the German, French, or British schools of geography and sometimes by all three together. Some maintain that it was in these three countries that the discipline was first institutionalized as something distinct from history and geology. Between the mid-19th century and the beginning of the 20th century, and in the context of the construction and redefinition of national states and the process of imperialism and colonial expansion, geographical knowledge was clearly related to the extension of political and economic power. As it was considered, geography offered the kind of knowledge that made it

possible to acculturate and integrate or control local populations.

During this period, human geography became a distinct program in the curriculum. For example, the first chair in human geography was set up in 1870 within the context of the unification of Germany, and under the responsibility of the geographer-philosopher, Friedrich Ratzel (1844–1904). France recognized the importance of teaching geography after the loss of the territories of Alsace-Lorraine to the Germans. This was France's context for the creation of the chair of human geography under Paul Vidal de la Blache (1854–1904).

Ratzel developed a project for anthropogeography based on the analysis of the influence of natural conditions on humanity. For Ratzel, the greater the attachment to the earth (as Ratzel called the territory) the greater would be the need for a society to maintain its physical possession. Ratzel believed that it was for this reason that the state was created. The analysis of the relations between state and space was one of the main topics in anthropogeography. The development of any society would imply, as he saw it, the need to increase the size of territory and hence to conquer new areas. One can readily see the seeds of Adolf Hitler's *Lebensraum* (expanding "living space") in this approach to the state.

On the other hand, the Frenchman de la Blache was critical of anthropogeography as an approach to human geography. Rather than being interested in the influence of natural conditions on societies, de la Blache sought to analyze how societies could challenge nature and come to develop an environment suited to their needs. Within this framework he formulated his concept of the *genre de vie* (lifestyle), understood as a historically constructed relationship built up by different human groups with their surroundings, based on the use of available technologies. This was a view that emphasized human abilities and influences in modifying the physical earth itself.

For this geographer, natural human regions and regional study was seen as an expression of lifestyle, which was the whole object of study of human geography. Seen in the light of this approach, for de la Blache, the map of France was the result of the harmonizing of its different regions. In the light of the theories and studies of de la Blache, the concept of a region (the study of the particular relation of a set of diverse elements in a given area) became one of the key concepts in human geography.

In Great Britain, the Royal Geographical Society was responsible for the institutional and financial or-

ganization of the two chairs in geography, one at Oxford University and the other at Cambridge University. The first was assumed by Halford J. MACKINDER (1861–1947). The second fell to Francis Guillermand (1852–1933). Mackinder considered that geography could be useful to statesmen since it is an integrating discipline, in which studies can be made of the causal relationships between man and the environment. These studies can be conducted in specific areas and have as their purpose the analysis of these relationships on a global scale.

Toward the end of the 19th century, biology was considered to be the most modern discipline. In the light of such thinking, the concept of geography as a natural science was the guarantee required for it to achieve qualification as a science. Thus, no one hesitated to qualify geography as a natural science, thus placing evolution at the heart of any geographic explanation.

For French geographers, human geography was a discipline that leads to knowledge of the relationship of societies with their environment. For Russian geographers, the purpose of geography in education was to reveal the battle of human beings with nature, thereby leading to a better understanding of the relationship between the two. Some Russians stressed that the study of human diversity implies showing what constitutes families of different peoples, bringing them together regardless of any racial differences, beliefs, or lifestyles. On the other hand, other geographers placed work as the mediator between the physical environment and society.

North American cultural geography presented by Carl SAUER (1889–1975) is one of the few proposals of that time that attempts to rise above a global and North American evolutionary framework (particularly as it was developed in the UNITED STATES by H. Barrows, T.G. Taylor, R.D. Salisbury along with W. DAVIS and E. Semple.). In fact, Sauer makes the whole concept of culture, linked to the anthropology, the key to the transformation of the natural landscape or the visible forms of nature into a cultural landscape.

### PRAGMATIC PERSPECTIVES

In the years after World War II and to the beginning of the Cold War, regional analyses of human geographies had become the principal activity conducted in the field.

As financial capital was directed to the reconstruction of postwar Europe, a group of planning organizations were attempting to define the best locations for

productive activities. They did this using a set of geographical engineering models that would define social problems before they became major challenges. The joining of the human geographies of political and economic perspectives led to the birth of a focus on pragmatic versus theoretical or descriptive studies. For most of the geographers following this line, mathematical language and models were considered to be the most appropriate methods for true science.

Human geographies that emphasized descriptive accounts were exchanged for a more statistical approach. Neoclassical models were formulated in the belief that subjects would behave rationally and with a view to seeking a maximization of earnings and opportunities. Now human geography became viewed as a discipline entrusted with spatial analysis. From this time on, spatial organization became the principal object of study of human geographers. The scientific base was to begin with an assumption that geographic space was to begin *de novo*—that is, without people or prior history. In short, the approach was, “All things being equal, then...” Within these assumptions, the planner could move freely within geographic space, the only variables would be questions of distance, direction, and connection (linkage). The geographic region was understood as the space in which internal differences are minimized and everything beyond its boundaries would be of much greater difference or variance.

Under the idea of pragmatic geography (as another subset of human geography) there were various trends. First, quantitative geographers studied the relations and interrelations of different geographic phenomena, local variations of physical landscape, and the impact of nature on societies and of the latter on the environment. These were all to be numerically expressed and understood. The second trend involved geographers who used systems theory. Hence it is given the name “systematic” or “modeling geography.” For example, the geographer Brian Berry defines models as key to the formulation of explanations. A third school of pragmatic geography is represented by a focus on the geography of perception. Drawing on the instruments of behavioral psychology, the followers of this trend try to analyze the subject valuation of space, both in the case of the behavior of the urban dweller and that of native African communities. It is focused on culture as the key to the creation of human geographies.

A part of the legacy of the approach of pragmatic geography has been the evolution of GEOGRAPHIC INFORMATION SYSTEMS (GIS), a field in which the concept of abstract space and the formulations of a mathemat-

ical character continue to play an important role. And it is a practice now widely used by many fields of science, both physical and social.

### RADICAL, CRITICAL HUMAN GEOGRAPHIES

As part of the sociology of its era, the decades of the 1960s and 1970s witnessed a major political convulsion in the field of human geography. In addition to the controversies surrounding the Vietnam War, it was a period during which many of the long-established European colonies in Africa achieved independence. Various social movements, such as those in defense of human rights, the rights of women, and the protests of an ecological character all appeared on the world scene and were especially intense in Europe and the United States. Many contemporary human geographers not only participated in these movements but also began to question their own practices. The crisis to be identified in geography was a symptom of other crises occurring in capitalism, politics, and science.

Some human geographers now considered that scientific knowledge should not only serve for the understanding of society, but should also help to guide and transform it. Positioning themselves simultaneously against both classical and quantitative geography, they tried to establish the basis of a new science that, as they saw it, would help create the basis of a new society. These geographers called themselves radicals in the UNITED STATES; in other contexts, such as the French, the Italian, the Spanish or the Latin American world, they were referred to as critical geographers.

Both the radical and critical schools of human geography followed the philosophical tenets of Marxism and stressed first and foremost the importance of economics (not the natural environment) when it comes to the interpretation of social dynamics. Second, they stressed the role of ideology in the production of knowledge, opposing the idea that there is any possibility of creating an objective or value-neutral science. Both the radical and the critical geographers reverted to the concept of space already worked upon by the pragmatic geographers in order to provide the social content it had consciously omitted (to be scientifically neutral) when formulated in the 1950s. Radical and critical geography was a shift to emphasizing human economics and philosophies in the creation of human geographies.

The approach known as active geography was opposed to the applied geography promoted over the decade of the 1950s. The first manifestation of this approach was found in *Géographie Active* (1964) the

name of a book written by Pierre George, Yves Lacoste, Bernard Kayser, and R. Guglielmo. This book undertook an analysis designed to reveal the contradictions of capitalism in different regional geography frameworks. Thus, a type of geography was formulated for regional analysis that would reveal inherent social contradictions such as poverty, malnutrition, and precarious housing. The proposal for active human geography also gave a new significance to actual fieldwork in the countryside. Thus, for example, in the Anglo-Saxon context, William Bunge proposed the organization of expeditions to communities living in conditions of poverty in order to help them overcome their situation, establishing a priority for social welfare over academic work.

Following the interdisciplinary exchanges that were opened up by the pragmatists, the radical and critical geographers exchanged ideas with other social sciences. This further removed human geography from its earlier emphasis on the physical environment. This exchange can be seen in the influence of the book by sociologist M. Castells, *La Question Urbaine* (1972), or the philosopher Henri Lefebvre's *La production de l'espace* (1974) on the urban geography of the period.

Among the radical geographers, one of their most representative works is *Urban Justice and the City* (1973) by David Harvey. Harvey questioned the liberal theories of the city and took on a socialist posture. He adopted the Marxist theory of rent in order to analyze the valuation of urban space. He then studied the use of the land in terms of use/value categories and exchange value. This sort of analysis enabled him to understand the active importance of spatial forms in social processes, an approach that he later developed in works dealing with the role of capital in the generation of unequal space usage and the compression of space/time. In one sense, it was a human geographic view of socialism rather than the traditional emphasis on how humans modify the physical environment.

For critical geographers, particularly in Latin America, one of the most important texts has been *Por uma Geografia Nova* (1978). The author, Milton Santos (1926–2001), showed that it was possible to conceive of personal ideas that could be applied to the interpretation of the third world. In effect, his analysis of the specific nature of urban processes in underdeveloped countries and his theory of banal space (the daily space for solidarity where men, living and feeling, have the opportunity to create a new history) are an example of this. Santos offers multiple ways of perceiving social space. First, space appears as a social product,

born of human action. Second, it signifies accumulated work, the incorporation of capital into land surface, which creates lasting forms known as “roughness.” These manifestations of “roughness” turn out to be space legacies that end up by influencing the pattern of contemporary action.

In this sense, spatial patterns are the product of past processes that also condition the future. Now there were human geographers who simply followed a modified version of the philosophical view *cogito, ergo sum*—“I think, therefore I am.”

## POSTMODERNISM

This approach led the human geographer Edward Soja to argue that while modern times have granted primacy in their explanatory role to history and time, postmodernism should open up the way to the social sciences, allowing them to achieve “the spatial turn.” Such an approach would be ideal for the analysis of changes and urban dynamics in cities such as Los Angeles. Such a city has particularly diverse geographic landscapes, constantly undergoing a process of change, and continually being reshaped by local and state practice, by internationalization, and by the globalization of work and trade. The city is produced, lived in, and provides for not only a middle class society, but also women, children, old folk, gays, lesbians, a multitude of ethnic minorities, the unemployed and the poor. With the approach prevailing until now, it was difficult to identify any urban fragments associated with the place of residence of certain social classes or the establishment of certain productive activities. In fact, global cities such as NEW YORK or LONDON are composed of a discontinuous collage of partial human geographic landscapes that no longer respond to the old center-periphery pattern. Approaches such as this may also be used for geographies of rural and regional environments.

Human geographers now have conducted a series of studies governed by this perspective. Some of the work along these lines includes: a) gender studies, b) postcolonial studies, and c) new cultural geographies.

Gender studies originated in the feminist movement of the 1960s. One of the basic points of these studies was the recognition that distinct gender geographies are to be found throughout all societies and all of history and that they always play a role in the organization of patterns of human geography. For example, in the geographic patterns resulting from the locations chosen by multinational clothing manufacturers and shoemakers in different parts of the world, there is a pattern that increasingly seeks female workers willing

to work at home on a part-time basis. This means there is a new kind of manufacturing geography, one not focused solely on large plants. Gender studies have also shown the need for a new kind of urban management and planning geography, an approach that looks at the needs for mobility and recreation of women and families.

Postcolonial geographic analysis begins by studying the human organization of space both under the colonial experience and how it exists today. The book *Orientalism*, written by Edward Said (1935–2003), is considered to be the basis for this field. Said maintained that the way in which we view the East from the West is the result of a Western cultural bias or mindset. Such a vision of the East was presented as exotic, sensual, culturally inferior, and backward—all of which supported imperial European expansion between 1870 and 1914.

In this context, colonial space (geographies) became an area of contact where diverse cultures met, collided, and fought. Postcolonial studies have also tried to listen to those who were the object of the colonial experience and had often been silenced by the European discourse.

They attempt to give space to voices that come from countries that went through colonial and live their consequences today (economic dependence, dictatorship, exclusion of women). Postcolonial researchers are also now being called upon to research image construction for the Muslim world and the immigrant Muslim populations, as reflected in political discourse and in the communications media. These findings are proving useful both for the justification of the new imperialism and for the imposition of restrictive migration policies, both aspects are used for understanding the political transformation and the globalization of the world.

## CULTURAL GEOGRAPHIES
